Lyapunov stability analysis of a string equation coupled with an ordinary differential system

Matthieu Barreau, Alexandre Seuret, Frédéric Gouaisbaut and Lucie Baudouin

Abstract—This paper considers the stability problem of a linear time invariant system in feedback with a string equation. A new Lyapunov functional candidate is proposed using augmented states which enriches and encompasses the classical functionals proposed in the literature. It results in tractable stability conditions expressed in terms of linear matrix inequalities. This methodology follows from the application of the Bessel inequality together with Legendre polynomials. Numerical examples illustrate the potential of our approach through three scenarios: a stable ODE perturbed by the PDE, an unstable open-loop ODE and an unstable closed-loop ODE stabilized by the PDE.

Index Terms—String equation, Ordinary differential equation, Lyapunov functionals, LMI.

I. INTRODUCTION

This paper presents a novel approach to assess stability of a heterogeneous system composed of the interconnection of a partial differential equation (PDE), more precisely a damped string equation, with a linear ordinary differential equation (ODE). While the topic of stability and control of PDE systems has a rich literature between applied mathematics [7], [16] and automatic control [18], the stability analysis (and the control) of such a coupled system belongs to a recent research area.

To cite a few related results, one can refer to [4], [5], [23] where an ODE is interconnected with a transport equation, to [25] for a heat equation, to [13] for the wave equation and to [27] for the beam equation.

Generally, the PDE is viewed as a perturbation to be compensated e.g. using a backstepping method proposed by [14], where infinite dimensional controllers are provided to cope with the undesirable effect of the PDE. Another interesting point of view relies on the converse approach: the ODE system can be seen as a finite dimensional boundary controller for the PDE (see [10], [20], [21]). A last strategy describes a robust control approach, aiming at characterizing the robustness of the interconnection [11].

In the present paper, we consider a damped string equation, i.e. a stable one-dimensional wave equation which is perturbed at its boundary by a stable or unstable ODE. The proposed method to assess stability is inspired by the recent developments on the stability analysis of time-delay systems based on Bessel inequality and Legendre polynomials [24]. Since time-delay systems represent a particular class of systems coupling a transport PDE with a classical ODE system (see for instance [2]), the main motivation of this work is to show how this methodology can be adapted to a larger class of PDE/ODE systems as demonstrated with the heat equation in [1].

Compared to the literature on coupled PDE/ODE systems, the proposed methodology aims at designing a new Lyapunov functional, integrating some cross-terms merging the ODE’s and the PDE’s usual terms. This new class of Lyapunov functional encompasses the classical notion of energy usually proposed in the literature by offering more flexibility. Hence, it allows us to guarantee stability for a larger set of systems, for instance, instable open-loop ODE and, for the first time to the best of our knowledge, even an unstable closed-loop ODE.

The paper is organized as follows. The next section formulates the problem and provides some general results on the existence of solutions and equilibrium. In Section 3, after a modeling phase inspired by the Riemann coordinates, a generic form of Lyapunov functionals is introduced, and its associate analysis leads to a first stability theorem. Then, in Section 4, an extension using Bessel inequality is provided. Finally, Section 5 discusses the results on three examples. The last section draws some conclusion and perspectives.

Notations: In this paper, \( \Omega \) is the closed set \([0,1]\) and \( \mathbb{R}^+ = [0, +\infty) \). Then, \((x, t) \mapsto u(x, t)\) is a multi-variable function from \( \Omega \times \mathbb{R}^+ \) to \( \mathbb{R} \). The notation \( u_t \) stands for \( \frac{\partial u}{\partial t} \). We also use the notations \( L^2 = L^2(\Omega; \mathbb{R}) \) and for the Sobolov spaces: \( H^n = \{ z \in L^2; \forall m \leq n, \frac{\partial^m z}{\partial x^m} \in L^2 \} \). The norm in \( L^2 \) is \( \| z \|^2 = \int_{\Omega} |z(x)|^2 \, dx \). For any square matrices \( A, B \), the operations ‘He’ and ‘diag’ are defined as follows: \( \text{He}(A) = A + A^T \) and \( \text{diag}(A, B) = [A, B] \). A symmetric positive definite matrix \( P \in \mathbb{R}^{n \times n} \) belongs to the set \( \mathbb{S}^n_+ \) or we write more simply \( P > 0 \).

II. PROBLEM STATEMENT

We consider the coupled system described by

\[
\begin{align*}
\dot{X}(t) &= AX(t) + Bu(1, t), \quad t \geq 0, \quad (1a) \\
u_{\Omega}(x, t) &= c^2 u_{xx}(x, t), \quad x \in \Omega, t \geq 0, \quad (1b) \\
u(0, t) &= K X(t), \quad t \geq 0, \quad (1c) \\
u_x(1, t) &= -c_0 u_t(1, t), \quad t \geq 0, \quad (1d) \\
u(x, 0) &= u^0(x), \quad u_t(x, 0) = v^0(x), \quad x \in \Omega, \quad (1e) \\
X(0) &= X^0, \quad (1f)
\end{align*}
\]

with the initial conditions \( X^0 \in \mathbb{R}^n \) and \((u^0, v^0) \in H^1 \times L^2 \) such that equations (1c) and (1d) are respected. They are then called “compatibles” with the boundary conditions. \( A, B \) and \( K \) are time-invariant matrices of appropriate size.

Remark 1: When no confusion is possible, parameter \( t \) may be omitted and so do the domains of definition.

This system can be viewed as an interconnection in feedback between a linear time invariant system (1a) and an infinite dimensional system modeled by a string equation (1b). The latter is a one dimension hyperbolic PDE, representing the
evolution of a wave of speed $c > 0$ and amplitude $u$. To keep
the content clear, the dimension of $x \mapsto u(x, \cdot)$ is assumed
to be one but the calculus are done as if it was a vector of
any dimension. The measure is the state $u$ at $x = 1$ which is
the end of the string and the control is a Dirichlet actuation
(equation (1c)) because it affects directly the state $u$ and not
its derivative. To be well-posed, another boundary condition
must be added. It is defined at $x = 1$ by $u_x(1) = -c_0 u(1)$. This
is a well-known damping condition for $c_0 > 0$ (see for
example [15]). A potential application would be the control
of a drilling system as presented in [3]. The control is given
at one end and the measure is done at the other end of the
drilling pit.

More generally, this system can be seen either as the control
of the PDE by a finite dimensional dynamic control law
generated by an ODE [6] or on the contrary the robustness of
a linear closed loop system with a control signal conveyed by
a damped string equation. On the first scenario, both the ODE
and the PDE are stable and the stability of the coupled system
is studied. The second case is with an unstable but stabilizable
ODE and the PDE is still stable. Finally, this paper focuses on
the stability analysis of closed-loop coupled system (1). This
differs from the backstepping methodology presented in [13]
where infinite dimensional control laws are designed to ensure
stability of a cascaded ODE-PDE systems.

A. Existence and regularity of solutions

This subsection is dedicated to the existence and regularity
of solutions $(X, u)$ to system (1). We consider the classical
norm on the Hilbert space $\mathcal{H} = \mathbb{R}^n \times H^1 \times L^2$
\[
\| (X, u, v) \|_{\mathcal{H}} = |X|^2 + \| u \|^2 + \epsilon^2 \| u_x \|^2 + \| v \|^2.
\]
This norm can be seen as the sum of the energy of the ODE
system and the one of the PDE.

Remark 2: A more natural norm for space $\mathcal{H}$ would be
\[
|X|^2 + \| u \|^2 + \| u_x \|^2 + \| v \|^2
\]
which is equivalent to $|X|^2 + \| u \|^2$. The norm used here makes the calculus easier in the sequel.

Once the space is defined, we can model System (1) using
the following linear unbounded operator $T : D(T) \to \mathcal{H}$:
\[
T(X, u, v) = \begin{pmatrix} AX + Bu(1) \\ \epsilon u_{xx} \end{pmatrix}
\]
\[
D(T) = \{ (X, u, v) \in \mathcal{H}, u(0) = KX, u_x(1) = -c_0 v(1) \}.
\]
This operator $T$ is said to be dissipative with respect to a
norm if its time-derivative along the trajectories generated by
$T$ is strictly negative. The aim of this paper is then to find
an equivalent norm to $\| \cdot \|_{\mathcal{H}}$ which allows us to refine the
dissipativity analysis of $T$. This equivalent norm is derived
from a general formulation of a Lyapunov functional, whose
parameters are chosen using a semi-definite programming
optimization process.

Beforehand, from the semi-group theory, we propose the following
result on the existence of solutions for (1).

Proposition 1: If there exists a norm on $\mathcal{H}$ for which the
linear operator $T$ is dissipative with $A + BK$ non singular,
then there exists a unique solution $(X, u, u_t)$ of system (1)
with initial conditions $(X^0, u^0, v^0) \in \mathcal{H}$ compatible with the
boundary conditions. Moreover, the solution has the following
regularity property: $(X, u, u_t) \in C(0, +\infty, \mathcal{H})$.

Proof: This proof follows the same lines than in [19]. Applying
Lumer-Phillips theorem (p103 from [26]), as the norm
is dissipative, it is enough to show that for all $\lambda \in (0, \lambda_{max})$
with $\lambda > 0$, the application $D(T) \subset R(\lambda I - T)$ where $R$
is the range operator. This is quite technical and has already
been done by Morgül in [19] for a slightly different system
considering a Neumann actuation. Let $(r, g, h) \in \mathcal{H}$, we want
to show that for this system, there exists $u(X, u, v) \in D(T)$ for
which the following set of equation is verified:
\[
\begin{align*}
\lambda X - AX - Bu(1) &= r, (2a) \\
u(x) - v(x) &= g(x), (2b) \\
u(x) - c^2 u_{xx}(x) &= h(x), (2c)
\end{align*}
\]
for all $x \in (0, 1)$ and a given $\lambda > 0$. Using equations (2b),
(2c) and the boundary conditions, we get:
\[
\forall x \in (0, 1), \quad u(x) = 2k_1 \sinh(\lambda - c^2 x) + Kxe^{-\lambda c^2 x} + G(x),
\]
where $G(x) = \int_0^x \frac{\lambda g(s) + h(s)}{\lambda} \sinh \left( \frac{\lambda}{c}(s - x) \right) ds$. $k_1 \in \mathbb{R}$
is a constant to be determined. Taking its derivative at the
boundary we get:
\[
u(1) = 2k_1 \cosh(\lambda - \lambda c^2) - \lambda - \lambda c^2 \lambda c^2 e^{-\lambda c^2} + G(1),\]
with $G (1) \in \mathbb{R}$ known. We also have $u_x(1) + c_0 v(1) = 0$
leading to $u(1) = G_1 + KX e^{-\lambda c^2} + G_2 \in \mathbb{R}$ and $f(y) = \left( 1 - \frac{\lambda c^2 e^{-\lambda c^2}}{\lambda (\sinh(y) + \cosh(y))} \right) e^{-y}$. Then using (2a), we get:
\[
\left( \lambda I_n - (A + BK f(\lambda c^2)) \right) X = r + BG_2.
\]
Since $f(\lambda c^2)$ tends to 1 when $\lambda$ tends to 0 and $A + BK$
is non singular, there exists $\lambda_{max} > 0$ such that $A + BK f(\lambda_{max} c^2)$ is non singular and
\[
\forall \lambda \in (0, \lambda_{max}), \quad \det \left( \lambda I_n - (A + BK f(\lambda c^2)) \right) \neq 0.
\]
Then, there is a unique $X \in \mathbb{R}^n$ for a given $(r, g, h) \in \mathcal{H}$.
We immediately get that $(X, u, v)$ is in $D(T)$. The for $\lambda \in (0, \lambda_{max})$, $D(T) \subset R(\lambda I - T)$. The regularity property falls
from Theorem 4.1.6 of [26].

B. Equilibrium point

An equilibrium $x_{eq} = (X_e, u_e, v_e) \in D(T)$ of System (1) is such that $T x_{eq} = 0 \in \mathcal{H}$, i.e. it verifies the following equations:
\[
\begin{align*}
0 &= AX_e + Bu_e(1), (3a) \\
0 &= \epsilon^2 \partial_x u_e(x), \quad x \in (0, 1), (3b) \\
v_e(x) &= 0, \quad x \in (0, 1), (3c) \\
u_e(0) &= KX_e, (3d) \\
\partial_x u_e(1) &= 0. (3e)
\end{align*}
\]
Using equation (3b), we get $u_e$ as a first order polynomial in
$x$ but in accordance to equation (3e), $u_e$ is a constant function.
Then, using equation (3d), we get $u_e = KX_e$. Equation (3a)
and the previous statement lead to: $(A + BK) X_e = 0$. We get
then the following proposition:

Proposition 2: An equilibrium $(X_e, u_e, v_e) \in \mathcal{H}$ of System
(1) verifies $(A + BK) X_e = 0$, $u_e = KX_e$, $v_e = 0$. Moreover,
if $A + BK$ is not singular, system (1) admits a unique equilibrium $(X_e, u_e, v_e) = (0, 1, 0, 0) = 0_H$.

Remark 3: In the previous subsection, we showed that $A + BK$ must be not singular to get uniqueness of the solution. This requirement is also related to the existence of a unique equilibrium.

III. A First Stability Analysis Based on Modified Riemann Coordinates

This part is dedicated to the construction of a Lyapunov functional candidate. We introduce therefore a new structure based on variables directly related to the states of System (1).

A. Modified Riemann coordinates

The PDE considered in System (1) is of second order in time. As we want to use some tools already designed for first order systems, we propose to define some new states using modified Riemann coordinates, which satisfy a set of coupled first order PDEs and diagonalize the operator. Let us introduce these coordinates, defined as follows:

$$
\chi(x) = \begin{bmatrix} u_t(x) + cu_x(x) \\ u_t(1 - x) - cu_x(1 - x) \end{bmatrix} = \begin{bmatrix} \chi^+(x) \\ \chi^-(1 - x) \end{bmatrix}.
$$

The introduction of such variables is not new and the reader can refer to articles [22], [3] or [8] and references therein about Riemann invariants. $\chi^+$ and $\chi^-$ are eigenfunctions of equation (1b) associated respectively to the eigenvalues $c$ and $-c$. Therefore, using $\chi^-(1 - x)$, the previous equation leads to a transport PDE for $x \in \Omega$:

$$
\forall t \geq 0, \forall x \in \Omega, \quad \chi_t(x, t) = c\chi_x(x, t). \tag{4}
$$

Remark 4: The norm of the modified state $\chi$ can be directly related to the norm of the functions $u_t$ and $u_x$. Indeed simple calculations and a change of variables give:

$$
\|\chi\|^2 = 2 \left(\|u_t\|^2 + c^2\|u_x\|^2\right). \tag{5}
$$

Remark 5: This manipulation does not aim at providing an equivalent formulation for System (1) but at identifying a manner to build a Lyapunov functional for System (1).

The second step is to understand how the extra-variable $\chi$ interacts with the ODE of System (1). Hence, we notice:

$$
\dot{X} = AX + B(u(1) - u(0)) + KX,
$$

$$
= (A + BK)X + B \int_0^1 u_x(x)dx.
$$

To express the last integral term using $\chi$, we note that:

$$
2c \int_0^1 u_x(x)dx = \int_0^1 \chi^+(x)dx - \int_0^1 \chi^-(x)dx.
$$

This expression allows us to rewrite the ODE system as

$$
\dot{X} = (A + BK)X + B\chi_0 \quad \text{where} \quad \chi_0 = \int_0^1 \chi(x)dx \quad \text{and} \quad B = \frac{1}{2c}B[1 \ - 1].
$$

The extra-state $\chi_0$ follows the dynamics:

$$
\dot{\chi}_0 = c \int_0^1 \chi_x(x)dx = c[\chi(1) - \chi(0)].
$$

The ODE dynamic can then be enriched by considering an extended system where $X_0$ is viewed as a new dynamical state:

$$
\dot{X}_0 = \begin{bmatrix} A + BK & B \\ 0_{2,n} & 0_2 \end{bmatrix} X_0 + \begin{bmatrix} 0_{n,2} \\ 0_{2,2} \end{bmatrix} \left(\chi(1) - \chi(0)\right), \tag{6}
$$

with $X_0 = [X^T \ \chi^T]_1^T$. Beware that $X_0$ is not the initial ODE data $X^0$.

Hence, associated to the original system (1), we propose a set of equation (4)-(6). They are linked to System (1) but enriched by extra dynamics aiming at representing the interconnection between the extended finite dimensional system and the two transport equations. Nevertheless, these two systems are not equivalent. The transport equation gives trajectories of $u_t$ and $u_x$ but $u$ can be defined within a constant. The second set of equations just induces a formulation for a Lyapunov functional candidate which is developed in the subsection below.

B. Lyapunov functional and stability analysis

The main idea is to rely on the auxiliary variables satisfying equations (4) and (6) to define a Lyapunov functional for the original system (1). The associated Lyapunov function of ODE (6) is a simple quadratic term on the state $X_0^T P_0 X_0$, with $P_0 \in \mathbb{S}_{+}^{n+2}$. It introduces automatically a cross-term between the ODE and the original PDE through $X_0$. Hence, the auxiliary equations of the previous part shows a coupling between a finite dimensional LTI system and an infinite dimension PDE seen as a transport equation. For the infinite dimensional part, inspired from the literature on time-delay systems [2], [8], we provide a Lyapunov functional:

$$
V(u) = \int_0^1 \chi^T(x) (S + xR) \chi(x)dx,
$$

with $S, R \in \mathbb{S}_{+}^2$. The use of the modified Riemann coordinates enables us to consider full matrices $S$ and $R$. As the transport described by the variable $\chi$ is going backward, $R$ is multiplied by $x$. Thereby, we propose a Lyapunov functional for system (1) expressed with the extended state variable $X_0$:

$$
V_0(X_0, u) = X_0^T P_0 X_0 + V(u). \tag{7}
$$

This Lyapunov functional is actually made up of three terms:

1) A quadratic term in $X$ introduced by the ODE;
2) A functional $V$ for the stability of the string equation;
3) A cross-term between $X_0$ and $X$ described by the extended state $X_0$.

The idea is that this last contribution is of interesting since we may consider the stability of System (1) with an unstable ODE part, stabilized thanks to the string equation. At this stage, a stability theorem can be derived using the Lyapunov functional $V_0$.

Theorem 1: Consider the system defined in (1) with a given speed $c$, a viscous damping $c_0 > 0$ with initial conditions $(X^0, u^0, v^0) \in H$ compatible with the boundary conditions. Assume there exist $P_0 \in \mathbb{S}_{+}^{n+2}$ and $S, R \in \mathbb{S}_{+}^2$ such that the linear matrix inequality $\Psi_0 < 0$ holds where

$$
\Psi_0 = \text{He} \left(Z_0^T P_0 F_0 - c \tilde{R}_0 + c \left(H_0^T (S + R) H_0 - G_0^T S G_0\right)\right) \tag{8}
$$
Then there exists a unique solution to System (1) and it is exponentially stable in the sense of norm $\|\cdot\|_H$, i.e. there exist $\gamma \geq 1, \delta > 0$ such that the following estimate holds:
\[
\forall t > 0, \|X(t)\|_H e^{-\delta t} \leq C e^{-\gamma e^{-\delta t}}
\]
(10)

Remark 6: Condition $\Psi_0 < 0$ includes a necessary condition given by $e_3 \Psi e_3 \preceq 0$, with $e_3 = \left[0_{n+2, n+2} \right]^T$, which is $h^T(S + R)h - g^T Sg \preceq 0$. This inequality is guaranteed if and only if the matrix $g^{-1} h$ has its eigenvalues inside the unit circle of the complex plane, i.e. $e_0 > 0$, which is consistent with the result on exponential stability presented in [12].

C. Proof of Theorem 1

The proof of stability is presented below.

1) Preliminaries: As a first step of this proof, let us introduce the following lemma that will be useful in the sequel.

Lemma 1: The following inequality holds:
\[
\|u\|^2 \leq 2\|u_0\|^2 + 2\|u(0)\|^2,
\]
\[\forall u \in H^1.\]

Proof: Since $u_0 \in L^2(\Omega)$, Young and Jensen inequalities imply that for all $x \in \Omega$:
\[
\|u(x)\|^2 = \left(\int_0^\infty u_s(s)ds - u(0)\right)^2 \leq 2 \int_0^\infty u_s^2(s)ds + 2\|u(0)\|^2.
\]

The proof of Theorem 1 consists in explaining how the fulfillment of LMI condition presented in Theorem 1 implies there exist a functional $V$ and three positive scalars $\varepsilon_1, \varepsilon_2$ and $\varepsilon_3$ such that the following inequalities hold:
\[
\varepsilon_1 \|(X, u, u_t)\|_H^2 \leq V(X, u) \leq \varepsilon_2 \|(X, u, u_t)\|_H^2,
\]
\[
\dot{V}(X, u) \leq -\varepsilon_3 \|(X, u, u_t)\|_H^2.
\]
(11)

The next paragraphs aim at proving (11) in order to obtain the convergence of the state to the equilibrium.

2) Well-posedness: If the conditions of Theorem 1 are satisfied, then the inequality $\Psi_0(1, 1) = e_1^T \Psi e_1 \preceq 0$ holds where $e_1 = \left[ I_{n+2} \right]^T$. After some simplifications, we get $He((A + BK)^T Q) \preceq 0$, for some matrix $Q$ depending on $R$, $S$ and $P_0$. This strict inequality requires that $A + BK$ is not singular and, in light of Propositions 1 and 2, the problem is indeed well-posed and $0_H$ is the unique equilibrium point. Furthermore, note that since $Q$ is not necessarily symmetric, matrix $A + BK$ does not have to be Hurwitz.

3) Existence of $\varepsilon_1$: The LMI conditions, $P_0 \succ 0$, $S \succ 0$ and $R \succ 0$ mean that there exists $\varepsilon_1 > 0$ such that for all $x \in [0, 1]$:
\[
P_0 \geq \varepsilon_1 \text{diag}(I_{n+2} + 2K^T K, 0_2),
\]
\[
S + xR \succeq S \succeq \varepsilon_1 \frac{2e^x}{1-e^x} I_2.
\]

These inequalities lead to:
\[
\begin{align*}
V_0(X_0, u) & \geq \varepsilon_1 (\|X_0\|^2 + \|KX\|^2 + \frac{2e^x}{1-e^x} \|\chi\|^2) \\
& + \int_0^1 \chi^T(x) (S + xR - \varepsilon_1 \frac{2e^x}{1-e^x} I_2) \chi(x)dx \\
& \geq \varepsilon_1 (\|X_0\|^2 + \|KX\|^2 + \frac{2e^x}{1-e^x} \|\chi\|^2).
\end{align*}
\]

Noting the boundary condition (1c) and norm equality (5), it becomes
\[
V_0(X_0, u) \geq \varepsilon_1 (\|X_0\|^2 + \|u\|^2 + \|u_0\|^2 + e^x \|u_x\|^2) \\
+ \frac{2e^x}{1-e^x} \|u_x\|^2 + \varepsilon_1 (2 \|u_x\|^2 + 2\|u(0)\|^2 - \|u\|^2).
\]

Then, we apply Lemma 1 to ensure that the last term is positive so that it yields $V_0(X_0, u) \geq \varepsilon_1 \|(X(0), u(0), u_t(0))\|_H^2$, which ends the proof of existence of $\varepsilon_1$.

4) Existence of $\varepsilon_2$: Since $P_0 \in S_{++}^{n+2}$ and $S, R \in S_{++}^n$, there exists $\varepsilon_2 > 0$ such that for $x \in (0, 1)$:
\[
P_0 \succeq \text{diag}(\varepsilon_2 I_n, \frac{\varepsilon_2}{4} I_2),
\]
\[
S + xR \succeq S + R \succeq \frac{\varepsilon_2}{4} I_2.
\]

From equation (7), we get:
\[
\begin{align*}
V_0(X_0, u) & \leq \varepsilon_2 (\|X_0\|^2 + \frac{1}{\varepsilon_2} X_0^T X_0 + \frac{1}{\varepsilon_0} \|\chi\|^2) \\
& + \int_0^1 \chi^T(x) (S + xR - \frac{\varepsilon_2}{4} I_2) \chi(x)dx \\
& \leq \varepsilon_2 (\|X_0\|^2 + \frac{1}{\varepsilon_0} \|\chi\|^2)
\end{align*}
\]
where we have used Jensen’s inequality which ensures that $X_0^T X_0 \preceq \|\chi\|^2$. The proof of the existence of $\varepsilon_2$ ends by using norm equality (5) so that we get
\[
V_0(X_0, u) \leq \varepsilon_2 (\|X_0\|^2 + \|u_t\|^2 + e^x \|u_x\|^2) \leq \varepsilon_2 \|(X(0), u(0), u_t(0))\|_H^2.
\]

5) Existence of $\varepsilon_3$: Differentiating $V_0$ in (7) along the trajectories of system (1) leads to
\[
\dot{V}_0(X_0, u) = H \left( \begin{bmatrix} X^T \nabla_0 \end{bmatrix}^T P_0 \begin{bmatrix} \nabla_u \end{bmatrix} \right) + \dot{\chi}(u).
\]

Our goal is to express an upper bound of $\dot{V}_0$ thanks to the extended vector $\xi_0$ defined as follows:
\[
\xi_0 = \begin{bmatrix} X^T \\ X_0^T \\ u_t(1) \\ cu_0(0) \end{bmatrix}^T.
\]

Let us first concentrate on $\dot{\chi}$. Equation (4) yields:
\[
\dot{\chi}(u) = 2c \int_0^1 \chi^T(x, t)(S + xR)\chi(x, t)dx.
\]

Integrating by parts the last expression leads to:
\[
\dot{\chi}(u) = c \left( \chi^T(1)(S + R)\chi(1) - \chi^T(0)S\chi(0) - \int_0^1 \chi^T(x)R\chi(x)dx \right).
\]

Then we note that $\dot{X} = N_0\xi_0, \dot{X}_0 = c(H_0 - G_0)\xi_0, \chi(1) = H_0\xi_0, \chi(0) = G_0\xi_0$, with $\xi_0$ defined in (13) and the matrices above in equation (9). We get $X_0 = F_0\xi_0$ and $X_0 = Z_0\xi_0$.
and the resulting expression for $\dot{V}_0$ is obtained:

$$
\dot{V}_0(X_0, u) = \xi_0^T (\mathbf{H} \left( Z_0^T P_0 F_0 \right) + c H_0^T (S + R) H_0 - cG_0^T S G_0) \xi_0 - c \int_0^1 \chi^T (x) R \chi (x) dx. \tag{16}
$$

Then, using the definition of matrix $\Psi_0$ given in (8), the previous expression can be rewritten as follows:

$$
\dot{V}_0(X_0, u) = \xi_0^T \Psi_0 \xi_0 + c X_0^T R X_0 - c \int_0^1 \chi^T (x) R \chi (x) dx. \tag{17}
$$

Since $R > 0$ and $\Psi_0 < 0$, there exists $\varepsilon_3 > 0$ such that:

$$
R \geq \frac{\varepsilon_3}{2} + \frac{c^2}{2 c^2} I_2,
$$

$$
\Psi_0 \leq -\varepsilon_3 \text{diag} \left( I_n + 2 K^T K, \frac{2 + c^2}{2 c^2} - I_2, 0_2 \right). \tag{18a}
$$

Using (18b) and the boundary condition $u(0) = K X$, equation (17) becomes:

$$
\dot{V}_0(X_0, u) \leq -\varepsilon_3 \left( |X|^2_n + 2 |u(0)|^2 \right) + c X_0^T \left( R - \frac{\varepsilon_3}{2} \frac{2 + c^2}{2 c^2} I_2 \right) X_0 - c \int_0^1 \chi^T (x) \left( R - \frac{2 + c^2}{2 c^2} I_2 \right) \chi (x) dx.
$$

So that we get by application of Jensen’s inequality:

$$
\dot{V}_0(X_0, u) \leq -\varepsilon_3 \left( |X|^2_n + 2 |u(0)|^2 \right) + \frac{c^2}{2} \left| \chi \right|^2. \tag{19}
$$

The most important part of the proof lies in the following trick. Since (5) holds, we get:

$$
\dot{V}_0(X_0, u) \leq -\varepsilon_3 \left( |X|^2_n + 2 |u(0)|^2 \right) - \varepsilon_3 \left( 2 |u(0)|^2 + 2 |u_x|^2 \right).
$$

Moreover, Lemma 1 ensures that the last term of the previous expression is negative so that we have $\dot{V}_0(X_0, u) \leq -\varepsilon_3 \left( |X|^2_n + 2 |u(0)|^2 \right) \eta$, which concludes this proof of existence.

6) Conclusion: Finally, there exist $\varepsilon_1, \varepsilon_2, \varepsilon_3 > 0$ such that equation (11) holds for a functional $\dot{V}_0$. Hence $\dot{V}_0(\cdot)$ is an equivalent norm of $\| \cdot \|_\eta$ which is strictly decreasing. It means, according to Propositions 1 and 2, that there exists a unique solution to System (1) converging in $\mathcal{H}$ to the solution equilibrium $0_\mathcal{H}$. These conditions also bring : $\forall t > 0, \dot{V}_0(X_0, u) + \frac{\varepsilon_3}{c^2} \dot{V}_0(X_0, u) \leq 0$ and

$$
\| (X(t), u(t), u_x(t)) \|^2_\mathcal{H} \leq \frac{\varepsilon_1}{\varepsilon_2} e^{-\frac{\varepsilon_2}{\varepsilon_1} t} \| (X(0), u(0), v(0)) \|^2_\mathcal{H},
$$

which shows the exponential convergence of all trajectories of system (1) to the unique equilibrium $0_\mathcal{H}$. In other words, the solution to System (1) is exponentially stable.

Remark 7: It is also worth noting that LMI (8) is affine with respect to matrices $A, B$, which allows us, in a straightforward manner, to extend this theorem to uncertain ODE systems subject, for instance, to polytopic-type uncertainties.

IV. EXTENDED STABILITY ANALYSIS

A. Main motivation

In the previous analysis, we have proposed an auxiliary system presented in (6) helping us to define a new Lyapunov functional for System (1). The notable aspect is that the term $X_0 = \int_0^1 \chi (x) dx$ appears naturally in the dynamics of System (1). In light of the previous work on integral inequalities by [24], this term can also be interpreted as the projection of the modified state $\chi$ over the set of constant functions in the sense of the canonical inner product in $L^2$. One may therefore enrich system (6) by additional projections of $\chi$ over the next Legendre polynomials, as one can read in [24] in the context of time-delay systems. The family of shifted Legendre polynomials, denoted $\{ L_k \}_{k \in \mathbb{N}}$ and defined over $(0, 1)$ by $L_k(x) = (-1)^k \sum_{l=0}^k \binom{k}{l} \binom{k+n}{l} x^l$ with $\binom{k}{l} = \frac{k!}{l! (k-l)!}$, forms an orthogonal family respect to the $L^2$ inner product (see [9] for more details).

B. Preliminaries

The previous discussion leads us to define additional vectors for any function $\chi$ in $L^2$:

$$
\forall k \in \mathbb{N}, \quad X_k = \int_0^1 \chi (x) L_k (x) dx,
$$

and the augmented vector $X_N$, for $N \in \mathbb{N}$, as follows:

$$
X_N = \left[ X^\top, X_0^\top, \cdots, X_N^\top \right]^\top. \tag{20}
$$

Following the same methodology as for Theorem 1, this specific structure leads us to introduce a new Lyapunov functional, inspired from (7), with $P_N \in \mathbb{S}^{2+N}$. Then, for each $k \in \mathbb{N}$:

$$
V_N(X_N, u) = X_N^\top P_N X_N + \mathcal{V}(u). \tag{21}
$$

In order to follow the same procedure, several technical extensions are required. Indeed, the stability conditions issued from the functional $\dot{V}_0$ are coming from Jensen’s inequality and an explicit expression of the time derivative of $X_0$. Therefore, it is necessary to provide an extended version of the Jensen inequality and of this differentiation rule. These technical steps are summarized in the two following lemmas.

Lemma 2: For any function $\chi \in L^2$ and symmetric positive matrix $R \in \mathbb{S}^{2}$, the following Bessel-like inequality holds for all $N \in \mathbb{N}$:

$$
\int_0^1 \chi^T (x) R \chi (x) dx \geq \sum_{k=0}^N (2k + 1) X_k^2 R X_k. \tag{22}
$$

This inequality includes Jensen’s inequality as the particular case $N = 0$, which was one of the key element in the proof of Theorem 1. This comment allows us to assert that the previous lemma is the appropriate extension of the Jensen’s inequality to address the stability analysis using the new Lyapunov functional (21) with the augmented state $X_N$.

The proof is based on the expansion of the positive scalar $\| R^{1/2} \chi_N \|^2$ where $\chi_N (x) = \chi (x) - \sum_{k=0}^N (2k + 1) X_k^2 L_k (x)$ can be interpreted as the error approximation between function $\chi$ and its orthogonal projection over the family $\{ L_k \}_{k \leq N}$.

The next lemma is concerned by the differentiation of $X_k$.

Lemma 3: For any function $\chi \in L^2$, the following expression holds for any $N \in \mathbb{N}$:

$$
\begin{bmatrix}
\dot{X}_0 \\
\dot{X}_N
\end{bmatrix} = c \{ N (1) - c \bar{X}_N \} - c L_N \begin{bmatrix}
X_0 \\
X_N
\end{bmatrix},
$$
where
\[ L_N = \begin{bmatrix} I_{n+2N+2} & 0_{n+2N+2,2} \end{bmatrix}, \quad Z_N = \begin{bmatrix} N_N^T & cZ_N^T \end{bmatrix}^T, \]
\[ N_N = \begin{bmatrix} A + BK & \tilde{B} & 0_{N,2(N+1)} \end{bmatrix}, \]
\[ Z_N = 1_N H_N + \bar{N}_N G_N - 0_{2N+2,n} L_N 0_{2N+2,2}, \]
\[ G_N = \begin{bmatrix} 0_{2N+2,n} & 2 \end{bmatrix} \begin{bmatrix} -\kappa \end{bmatrix}, \quad H_N = \begin{bmatrix} 0_{2N+2,n} & 2 \end{bmatrix} \begin{bmatrix} 0 \end{bmatrix} N_N, \]
\[ \tilde{R}_N = \text{diag}(0_n, R, 3R, \ldots, (2N+1)R, 0_2), \]
and where matrices \( L_N, 1_N \) and \( \bar{N}_N \) are given in (23). Then, the coupled infinite dimensional system (1) is exponentially stable in the sense of norm \( \| \cdot \|_2 \) and there exists \( \gamma > 1 \) and \( \delta > 0 \) such that the energy estimate (10) holds.

Remark 8: Remark 6 also applies for this theorem. That means \( c_0 \) must be strictly positive. In other words, these theorems cannot ensure the stability if the PDE is undamped.

Remark 9: Note that Theorem 2 with \( N = 0 \) leads exactly to the same conditions as presented in Theorem 1.

Remark 10: Following [24] which shows that this methodology introduces a hierarchy in the case of time-delay systems, we also have the same characteristic. In other words, the sets
\[ C_N = \left\{ c > 0 \text{ s.t. } \exists P_N \in \mathbb{S}^{n+2(N+1)}_+, \quad S, R \in \mathbb{S}^2_+, \quad \Psi_N < 0 \right\} \]
which represents the set of parameters \( c \) such that the LMI of Theorem 2 is feasible for a given system (1) and for a given \( N \in \mathbb{N} \) satisfy the following inclusion \( C_N \subseteq C_{N+1} \). That means, if there exists a solution to Theorem 2 at an order \( N_0 \), then there also exists a solution for any order \( N \geq N_0 \). The proof is very similar to the one given in [24]. We can proceed by induction with \( P_{N+1} = \begin{bmatrix} P_N & 0 & 0 \\ 0 & 0 & \varepsilon I_2 \end{bmatrix} \) and a sufficiently small \( \varepsilon > 0 \). Then, \( \Psi_N < 0 \Rightarrow \Psi_{N+1} < 0 \). The calculus are tedious and technical and we do not intend to give them in this article.

D. Proof of Theorem 2

The proof of dissipativity follows the same line as in Theorem 1 and consists in proving the existence of positive scalars \( \varepsilon_1, \varepsilon_2 \) and \( \varepsilon_3 \) such that the functional \( V_N \) verifies the inequalities given in (11).

1) Well-posedness: Using a similar reasoning as in Theorem 1, a necessary condition for LMI (24) to be verified is that \( A + BK \) is non singular. Then, according to Propositions 1 and 2, the problem is well-posed and \( \mathcal{H}_N \) is the unique equilibrium.

2) Existence of \( \varepsilon_1 \): It strictly follows the same line as in Theorem 1 and is therefore omitted.

3) Existence of \( \varepsilon_2 \): Since \( P_N, S, R > 0 \), there exists \( \varepsilon_2 > 0 \) such that:
\[ P_N \succeq \text{diag} \left\{ \varepsilon_2 I_2, \varepsilon_2 \text{diag} \left\{ (2k+1)I_N \right\}_{k \in \mathbb{N}}, S \right\} \]
\[ (S + xR) \succeq S + R \geq \frac{\mu_2^2}{4} I_2, \quad \forall x \in (0, 1). \]

From equation (21), we get:
\[ V_N(X_N, u) \leq \varepsilon_2 |X_N|^2 + \varepsilon_2 \left( \sum_{k=0}^{N} (2k+1)X_n^T X_k + ||\chi||^2 \right) \]
\[ \leq \varepsilon_2 \left( |X_n|^2 + \frac{1}{2} ||\chi||^2 \right). \]

While the first inequality is guaranteed by the constraint \( (S + xR) \succeq \frac{\mu_2^2}{4} I_2 \), for all \( x \in (0, 1) \), the second result comes from the application of Bessel inequality (22). Therefore, following the same procedure as in the proof of Theorem 1 after equation (12), there indeed exists \( \varepsilon_2 > 0 \) such that:
\[ V_N(X_N, u) \leq \varepsilon_2 ||(X_N, u)||^2_H. \]

4) Existence of \( \varepsilon_3 \): Differentiating \( V_N \) defined in (21) along the trajectories of system (1) leads to:
\[ \dot{V}_N(X_N, u) = \text{He} \left( \begin{bmatrix} \dot{X}_0 \\ \dot{X}_n \end{bmatrix}^T P_N \begin{bmatrix} \dot{X}_0 \\ \dot{X}_n \end{bmatrix} + N \right) + \dot{\Psi}_N. \]

The goal here is to find an upper bound of \( \dot{V}_N \) using the following extended state:
\[ \xi_N = \begin{bmatrix} X_N^T & u_1(1) & u_1(0) \end{bmatrix}. \]

Using equation (15) and Lemma 3, we note that \( X_N = F_N \xi_N, \quad \dot{X}_N = Z_N \xi_N, \quad \dot{\Psi}_N = \Psi_N N_N, \quad \dot{H}_N = H_N^T N_N, \quad \dot{G}_N = G_N N_N \) where the matrices \( F_N, Z_N, H_N, G_N \) are given in (25). Then we can write:
\[ \dot{V}_N(X_N, u) = \xi_N^T \Psi_N \xi_N + c \sum_{k=0}^{N} \dot{X}_k^T (2k+1)R \dot{X}_k \]
\[ - c \int_{0}^{1} \chi^T(x) R \chi(x) dx. \]

Since \( R > 0 \) and \( \Psi_N < 0 \), there exists \( \varepsilon_3 > 0 \) such that:
\[ R \succeq \frac{\varepsilon_3}{2} \frac{x^2 + 2}{x^2} I_2, \]
\[ \Psi_N \preceq -\varepsilon_3 \text{diag} \left\{ I_N + K^T K, \quad \frac{2 + c^2}{2c^2} \text{diag} \{ I_2, 3I_2, \ldots, (2N+1)I_2 \}, 0_2 \right\}. \]

Using (27) and Bessel’s inequality, equation (26) becomes:
\[ \dot{V}_N(X_N, u) \leq -\varepsilon_3 \left( |X_n|^2 + 2 |u(0)|^2 + \frac{2 + c^2}{2c^2} ||\chi||^2 \right), \]
which is similar to equation (19) in the proof of Theorem 1. Therefore, following the same procedure, we obtain
\[ \dot{V}_N(X_N, u) \leq -\varepsilon_3 ||(X_N, u)||^2_H. \]
to keep its stability behavior. Another important thing to notice is the hierarchy property i.e. the decrease of $c_{\text{min}}$ as $N$ increases. The curve denoted “Freq” is obtained using a frequential analysis and displays the exact stability area. This exact method will be explained in another paper but do not use Lyapunov arguments. For this example, as $N$ increases, the stability area is converging to the exact one.

B. Problem (1) with $A + BK$ Hurwitz and $A$ with unstable eigenvalues.

This time, the system is described by the following matrices:

$$A = \begin{bmatrix} 0 & 1 \\ -2 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad K = \begin{bmatrix} -10 & 2 \end{bmatrix}. \quad (29)$$

As $A$ is not Hurwitz, we are studying the stabilization of the ODE through a communication modeled by the wave equation. For the same reason than before, the wave must be fast enough for the control not to be too much delayed but also with a moderated damping to transfer the state variable $X$ through the PDE equation. Intuitively, we are lead to introduce a trade-off between $c_{\text{min}}$ and $c_0$, introducing then a $c_{0,\text{max}}$ as it is possible to see in Figure 1b.

Some numerical simulations have been done on this example. Figure 1b shows that for System (29) with $c_0 = 0.15$, the minimum wave speed is $c_{\text{min}} = 6.83$. The numerical stability can also be seen in Figure 2 and indeed, the system is at the boundary of the stable area in Figure 2b and unstable for smaller values of $c$. The results coming from the exact criterion and Theorem 2 are close even for small $N$. That means the stability area provided with $N = 1$ is a good estimation of the maximum stability set.

C. Problem (1) with $A$ and $A + BK$ not Hurwitz.

Consider an open loop unstable system defined by:

$$A = \begin{bmatrix} 0 & 1 \\ -2 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad K = \begin{bmatrix} 1 \end{bmatrix}. \quad (30)$$

Gain $K$ has been chosen such that the closed loop is also unstable. Surprisingly, the proposed algorithm give some couples $(c, c_0)$ for which the whole System (1) is stable. The results are depicted in Figure 1c. Notice that for Theorem 1 (or Theorem 2 with $N = 0$), the LMIs do not give any stability results. For $N \geq 1$, there is a stability area for which the slope of the right asymptotic branch is decreasing at each order. Hence, it appears that the introduction of the string equation in the feedback loop helps the stabilization of the closed loop system. For $N = 1$, the stability area is quite far from the maximum one but as $N$ increases, this gap reduces significantly.

VI. Conclusion

A hierarchy of stability criteria has been provided for the stability of systems described by the interconnection between a finite dimensional linear system and an infinite dimensional ODE modeled by a string PDE. The proposed methodology relies on an extensive use of Bessel’s inequality which allows us to design a new an accurate Lyapunov functional. This new class encompasses the classical notion of energy proposed in that case. In particular, the stability of the closed-loop or open-loop system is not a requirement anymore. Future works will include the study of robustness of this approach and controller design.
A. Proof of Lemma 3

For a given integer \( k \) in \( \mathbb{N} \), the differentiating of \( \hat{x}_k \) along the trajectories of (4) yields
\[
\dot{\hat{x}}_k = c \int_0^1 \chi_k(x) \mathcal{L}_k(x) dx.
\]
Then, integrating by parts, we get
\[
\dot{\hat{x}}_k = c \left( \chi_k(x) \mathcal{L}_k(x) \right)_0^1 - \int_0^1 \chi_k(x) \mathcal{L}_k'(x) dx.
\]
(31)

In order to derive the expression of \( \dot{\hat{x}}_k \), we will use the following properties of the Legendre polynomials. On the one hand, the values of Legendre polynomials at the boundaries of \([0 1]\) are given by \( \mathcal{L}_k(0) = (-1)^k \) and \( \mathcal{L}_k(1) = 1 \). On the other hand, the Legendre polynomials verifies the following differentiation rule for \( k > 0 \):
\[
\frac{d}{dx} \mathcal{L}_k(x) = \sum_{j=0}^{k-1} (2j+1)(1-(-1)^{j+k}) \mathcal{L}_j(x)
\]
Hence, injecting these expressions into (31) leads to:
\[
\dot{\hat{x}}_k = c \left( \chi_k(1,t) - (-1)^k \chi_k(0) \right) - c \sum_{j=0}^{N} \ell^k j \chi_j,
\]
where the coefficient \( \ell^k j \) are defined in equation (23). The end of the proof consists in gathering in the previous expression from \( k = 1 \) to \( k = N \), leading to the definition of matrices \( L_N, \mathbb{1}_N \) and \( \mathbb{1}_N \) given in (23).

REFERENCES
