Abstract—A suboptimal algorithm to fixed-interval and fixed-lag smoothing for Markovian switching systems is proposed. It infers a Gaussian mixture approximation of the smoothing pdf by combining the statistics produced by an IMM filter into an original backward recursive process. The number of filters and smoothers is equal to the constant number of hypotheses in the posterior mixture. A comparison, conducted on simulated case studies, shows that the investigated method performs significantly better than equivalent algorithms.

Index Terms—Nonlinear Markovian switching systems; Interacting Multiple Model (IMM) filtering and smoothing; Rauch-Tung-Striebel formulae; Target tracking.

I. INTRODUCTION

MANY estimation or change detection problems are stated in the context of discrete-time jump Markov systems. Such systems are described by a bank of state space models, sharing the same state vector and corresponding to admissible modes of operation, together with a finite-state Markov chain featuring the transitions between modes. At each time $k$, the exact posterior probability density function (pdf) of the state vector conditioned on the measurements up to time $k'$ comes as a mixture of the set of all posterior pdfs conditioned on the observations up to $k'$ and on the possible mode sequences up to $k$, weighted by the posterior probability of these mode sequences. The computational complexity thus grows exponentially with $k$, so that approximations are needed to make the problem tractable [1][2].

In the filtering context, i.e. when $k=k'$, the number of hypotheses composing the above mixture can be reduced by merging those ones which are conditioned on similar mode sub-sequences up to time $k-n$. Generalized Pseudo-Bayesian filters of order $n$ (GPB$_n$) fall into this paradigm. For a bank of $M$ models, they involve $M^n$ filters. However, the most standard approach is undoubtedly the Interacting Multiple Model (IMM) filter [3], which propagates over time a $M$-hypotheses Gaussian mixture approximation to the posterior pdf at the complexity of GPB$_1$, but with a performance similar to GPB$_2$. Though initially designed for linear jump Markov systems, GPB$_2$ and IMM are widely used in the nonlinear case [4][5]. They can rely on extended [6] or unscented [7] (mode-conditioned) Kalman filters, or can be applied to non-Gaussian state-space models with particle filters [8]. IMM filtering is still an active research area, see for instance its recent independent extensions to heterogeneous-order models, i.e. to models which share only parts of their state vectors [9][10].

Fixed-interval smoothing refers to estimating the posterior pdf of the state vector at each time $k$ when measurements are assimilated over a fixed interval of length $T \geq k$. In contrast, fixed-lag smoothing considers the estimation of the state posterior pdf at each time $k$ from measurements up to $k+n$, where $n$ denotes the fixed lag length. Smoothing constitutes a fundamental problem as it helps to improve the estimation performance in comparison to filtering, though at the cost of some delay. In the field of target tracking for instance, delivering a location estimate by assimilating subsequent observations drastically reduces the associated error [11]. In the single-model non-Gaussian case, many schemes were considered, either based on particle filters [12], [13], [14], [15] or within the Random Finite Set paradigm [16]. Under Gaussian or Gaussian sum approximations with jump Markov systems, closed-form solutions to fixed-interval smoothing were proposed in [17], [18], [19].

The aim of this work is to show how the quantities produced by a forward-time IMM filter up to time $k'$ enable a closed-form approximation of the smoothing posterior density at times $k \leq k'$ by requiring only $M$ filters/smoothers for a bank of $M$ models. The proposed method extends the papers [20], [21] in that it enriches the original algorithm. In comparison, [18], [17] run $M^2$ smoothers for a bank of $M$ models. Ref. [19] runs $M$ smoothers but displays significantly lower performances than the investigated method.

The paper is organized as follows. Section II states a fixed-interval multiple model smoothing problem. Then, Section III reviews the theoretical foundations of the proposed strategy and positions it with respect to the literature. The main result, i.e. a constructive IMM-based fixed-interval smoothing algorithm, constitutes Section IV. Fixed-lag smoothing is considered in Section V. After simulation examples in Section VI comparing the proposed method to the equivalent existing algorithms [17], [18], [19], the paper ends with a conclusion and prospects.

II. PROBLEM STATEMENT

Notations are standard. $(\cdot)^T$ denotes the transpose operator. $P(.)$, $p(.)$ and $E[\cdot]$ respectively term a probability, a probability density function (pdf), and an expectation. $\mathcal{N}(\bar{x},X)$ stands for the (real) Gaussian distribution with mean $\bar{x}$ and covariance $X$ and $\mathcal{N}(x,\bar{x},X)$ is the associated pdf on $x$. The weighted squared norm $||a||_R^2 = a^T Ra$, with $R$ a symmetric positive definite matrix, is also referred to throughout the text.
The considered nonlinear jump Markov system admits $M$ modes, which constitute the set $\mathcal{M}$. At each time $k$, $m_k = j$ or $m_k = m'$ denotes the event that mode $j \in \mathcal{M}$ is in effect during the sampling period $[t_{k-1}, t_k]$. The sequence of modes follows an homogeneous finite-state Markov chain. Under the event $m_k = j$, the dynamics of the base (continuous) state $x_k$ and its relationship with the measurement $z_k$ are described by the stochastic nonlinear state space model

$$x_k = f_j(x_{k-1}) + q_{k-1}^j, \quad z_k = h_j(x_k) + r_k,$$

where $f_j(\cdot), h_j(\cdot)$ are given and $q_{k-1}^j, r_k$ account for dynamics and measurement noises. The global (hybrid) state vector at time $k$ will henceforth be termed $\xi_k = (x_k, m_k)$. $\xi_k$ will stand for $(x_k, m_k)$.

The (given) initial and transition probabilities of modes are

$$P(m_0^j) = \mu_j^0; \quad P(m_{k+1}^j | m_k) = \pi_{jj}.$$

Similarly, conditioned on mode $j$, the base state vector at initial time $k = 0$ and the noises are assumed jointly Gaussian and of (given) statistics, with $\delta_{k,k'}$ the Kronecker symbol,

$$\forall k, k', E \left[ \begin{array}{c} x_0|m_0^j \\ q_0^j \end{array} \right] = \left[ \begin{array}{c} x_{0|0}^j \\ 0 \end{array} \right],$$

$$E \left[ \begin{array}{c} (x_{0|0}^j - x_{0|0}) \\ (Q_{0|0}^j - Q_0) \end{array} \right] = \left[ \begin{array}{c} P_{0|0}^j \\ 0 \end{array} \right].$$

As a result, the pdf of the base state $x_0$ at initial time is a Gaussian mixture. The transition and observation densities associated to (1) and conditioned on the active mode $m_k^j$ in the sampling interval $[t_{k-1}, t_k]$ write as

$$p(x_k|x_{k-1}, m_k^j) = \mathcal{N}(x_k; f_j(x_{k-1}), Q_j^j),$$

$$p(z_k|x_k, m_k^j) = \mathcal{N}(z_k; h_j(x_k), R_j^j).$$

As aforementioned, a mixture with an exponentially increasing number of hypotheses (densities) would be required in the filtering pdf at further time $k$, in that

$$p(x_k|z_{1:k}) = \sum_{j=0}^{M-1} p(x_k|m_0 = j_0, z_{1:k}) P(m_0 = j_0) = \sum_{j=0}^{M-1} p(x_k|m_j^j, z_{1:k}) \pi_j,$$

where $v_{a,b}$ is a shortcut for the sequence $v_a, \ldots, v_b$ between times $a$ and $b$. A similar exponential complexity in the number of modes occurs in the exact form of the smoothing density, be it fixed-interval (i.e. $p(x_k|z_{1:T})$, with $T \geq k \geq 0$ the fixed interval length), fixed lag (i.e. $p(x_k|z_{1:k+n})$, with $n \geq 1$ the fixed lag length) or fixed-point (i.e. $p(x_k|z_{1:k})$, with $j$ fixed and $k \geq j$).

As in the single-model case [2], two views can be adopted for fixed-interval smoothing. Ref. [22] consists in fusing the estimates and covariances produced by a forward conventional IMM filter and a modified backward IMM filter. Some difficulties lie in the need to set an inverse dynamics model, especially if (1) is nonlinear, and initialize the backward filter with a flat prior so as to prevent the assimilation of common data into both filters. More recently [18] proposed a second smoothing scheme based on a GPB2 running $M^2$ forward filters whose estimates are recombined through a Rauch-Tung-Striebel (RTS) backward-time recursion [23] with $M^2$ smoothers. In comparison to the above two-filter strategy, this approach allows the use of non-invertible dynamics models. Moreover the backward-time pass is simply initialized with the filtered estimate at the end of the fixed interval. This paper rather follows this alternative viewpoint of IMM-based smoothing through RTS backward-time recursions.

### III. Theoretical Foundations

This section thoroughly reviews the theoretical foundations of the Interacting Multiple Model filtering and of the possible fixed-interval smoothing backward-time recursions.

#### A. The Interacting Multiple Model filter

The recursion cycle of the celebrated IMM filter was first outlined in [3]:

1. $\forall i \in \mathcal{M}, \{p(m_k^i|z_{1:k})\} \mathcal{M} \xrightarrow{\text{Prediction}} p(m_{k+1}^i|z_{1:k})$
2. $\forall i \in \mathcal{M}, \{p(x_k|m_k^i, z_{1:k})\} \mathcal{M} \xrightarrow{\text{Interaction}} p(x_{k+1}|m_{k+1}^i, z_{1:k})$
3. $\forall i \in \mathcal{M}, \{p(x_k|m_k^i, z_{1:k})\} \mathcal{M} \xrightarrow{\text{Prediction}} p(x_{k+1}|m_{k+1}^i, z_{1:k})$
4. $\forall i \in \mathcal{M}, \{p(x_{k+1}|m_k^i, z_{1:k})\} \mathcal{M} \xrightarrow{\text{Update}} p(x_{k+1}|m_{k+1}^i, z_{1:k+1})$
5. $\forall i \in \mathcal{M}, \{p(m_k^i|z_{1:k})\} \mathcal{M} \xrightarrow{\text{Update}} p(m_k^i|z_{1:k+1})$

The first step of the cycle should be read as “Compute the predicted mode probability $p(m_k^i|z_{1:k})$ $\forall i \in \mathcal{M}$ at time $k + 1$ from the set of posterior mode probabilities $\{p(m_k^i|z_{1:k})\} i \in \mathcal{M}$ at time $k$”, and so forth. The IMM filter enables the propagation over time of approximations to the mode probabilities $\{\mu_{ik}^j \approx p(m_k^i|z_{1:k})\} i \in \mathcal{M}$ and of Gaussian approximations to the mode-conditioned filtering pdfs $\{p(x_k|m_k^i, z_{1:k}) \approx \mathcal{N}(x_k; \hat{x}_{k|k}^i, P_{k|k}^i)\} i \in \mathcal{M}$, so that

$$p(x_k|z_{1:k}) \approx \sum_{i,j} \mu_{ik}^j \mathcal{N}(x_k; \hat{x}_{k|k}^i, P_{k|k}^i).$$

Its reasonable complexity comes from its internal computation of the mixing probabilities $\{\mu_{ik}^j \approx p(m_k^i|z_{1:k})\} i,j \in \mathcal{M}, \mathcal{I}, \mathcal{M}$, from which Gaussian approximations to the mode-conditioned prior pdfs $\{p(x_k|m_k^i, z_{1:k}) \approx \mathcal{N}(x_k; \hat{x}_{k|k}^i, P_{k|k}^i)\} i \in \mathcal{M}$ are deduced. Starting from these last pdfs, only $M$ independent filters (matched to the modes $\{m_{k+1}^i = i\} i \in \mathcal{M}$) need to be run between times $k$ and $k + 1$ in order to get

$$p(x_{k+1}|m_{k+1}^i, z_{1:k+1}) \approx \mathcal{N}(x_{k+1}; \hat{x}_{k+1|k}^i, P_{k+1|k}^i).$$

and update $\mu_{ik+1|k}^j = P_2(m_{k+1}^i|z_{1:k+1}) \mu_{ik}^j$, leading to $p(x_{k+1}|m_{k+1}^i, z_{1:k+1})$.

#### B. Smoothing using backward-time recursions

The posterior state densities $\{p(x_k|m_k^j, z_{1:T})\} i \in \mathcal{M}$ and mode probabilities $\{p(m_k^j|z_{1:T})\} i \in \mathcal{M}$ at time $T$ are the starting point. Given $\{p(x_k|m_k^j, z_{1:T})\} i \in \mathcal{M}$ and $\{p(m_k^j|z_{1:T})\} i \in \mathcal{M}$, the smoothing steps of the backward recursion can be conducted in three ways. The first two are drawn from the existing literature while the last one is the new approach investigated in this paper.
Backward smoothing recursion - SR1:

1. \( \forall (i, j) \in \mathcal{M}^2, p(x_{k+1}|m_i^{k+1}, z_{1:T}) \) → \( p(x_k|m_i^k, z_{1:T}) \)

2. \( \forall j \in \mathcal{M}, \{p(x_k|m_i^k, z_{1:T})\}_{i \in \mathcal{M}} \) → \( p(x_k|m_i^k, z_{1:T}) \)

3. \( \forall j \in \mathcal{M}, \{P(m_i^k|z_{1:T})\}_{i \in \mathcal{M}} \) → \( P(m_i^k|z_{1:T}) \)

This recursion cycle was proposed in [17] and [18]. It uses a total of \( M^2 \) smoothers for \( M \) admissible modes. More specifically, step 1 writes as:

\[
\forall (i, j) \in \mathcal{M}^2, p(x_k|m_i^k, z_{1:T}) = p(x_k|m_i^k, z_{1:T}) \int_{x_{k+1}} p(x_{k+1}|x_k, m_i^{k+1})p(x_{k+1}|m_i^{k+1}, m_j^{k}, z_{1:T}) \, dx_{k+1}
\]

where \( p(x_{k+1}|x_k, m_i^{k+1}) \) is the transition density between \( k \) and \( k + 1 \) at time \( k + 1 \). The densities \( p(x_k|m_i^k, z_{1:T}) \) and \( p(x_{k+1}|m_i^{k+1}, m_j^{k}, z_{1:T}) \) are computed by a forward GPB2 filter. Finally, the smoothed density \( p(x_{k+1}|m_i^{k+1}, m_j^{k}, z_{1:T}) \) is approximated by \( p(x_{k+1}|m_j^{k+1}, z_{1:T}) \) so as to start the recursion cycle.

Backward smoothing recursion - SR2:

1. \( \forall j \in \mathcal{M}, p(x_k|m_i^k, z_{1:T}) = \sum_{i \in \mathcal{M}} p(x_k|m_i^k, m_j^{k+1}, z_{1:T})P(m_i^{k+1}|m_j^{k}, z_{1:T}) \)

The authors claim that in the first term of the sum “the condition on \( m_j^k \) [..] can be ignored due to Markov property” so that \( p(x_k|m_i^k, m_j^{k+1}, z_{1:T}) = p(x_k|m_i^k, z_{1:T}) \) [19, Eq. 12]. Incidentally, this equality precludes the exponentially growing complexity of the problem. It should be rather considered as an approximation like in [17] and [18]. The development of step 2 is then conducted using the equality [19, Eq. 11]:

\[
\forall j \in \mathcal{M}, p(x_k|m_i^k, z_{1:T}) = p(x_k|m_i^k, z_{1:T}) \int_{x_{k+1}} p(x_{k+1}|x_k, m_i^{k})p(x_{k+1}|m_i^{k}, z_{1:T}) \, dx_{k+1}
\]

The authors further claim that “the term \( p(x_{k+1}|x_k, m_i^{k}) \) .. corresponds to the state transition density of model \( m_i^k \)”. However, this contradicts the hypothesis of [19, Eq. 1] in that \( m_i^k \) terms the active mode that governs the state transition between \( k - 1 \) and \( k \). This last hypothesis is used in the present paper (see (1) and (5)) and in the cited references too.

Backward smoothing recursion - SR3:

The present paper investigates an alternative method with a linear number of smoothers.

1. \( \forall i \in \mathcal{M}, p(x_{k+1}|m_i^{k+1}, z_{1:T}) \) → \( p(x_i|m_i^k, z_{1:T}) \)

2. \( \forall j \in \mathcal{M}, \{p(x_k|m_i^k, z_{1:T})\}_{i \in \mathcal{M}} \) → \( p(x_k|m_i^k, z_{1:T}) \)

3. \( \forall j \in \mathcal{M}, \{P(m_i^k|z_{1:T})\}_{i \in \mathcal{M}} \) → \( P(m_i^k|z_{1:T}) \)

The smoothing equation of the first step is now given by:

\[
\forall i \in \mathcal{M}, p(x_k|m_i^{k+1}, z_{1:T}) = p(x_k|m_i^{k+1, z_{1:T}}) \int_{x_{k+1}} p(x_{k+1}|x_k, m_i^{k+1})p(x_{k+1}|m_i^{k+1, z_{1:T}}) \, dx_{k+1}
\]

where \( p(x_k|m_i^{k+1, z_{1:T}}) \) and \( p(x_{k+1}|m_i^{k+1, z_{1:T}}) \) are computed by an IMM filter. The pdf \( p(x_k|m_i^{k+1, z_{1:T}}) \) is known from the previous recursion and \( p(x_{k+1}|x_k, m_i^{k+1}) \) is the genuine transition density between \( k \) and \( k + 1 \) as \( m_i^{k+1} \) is active over the sampling interval \( (k, k + 1) \). The other equations of this algorithm are detailed in the following section.

IV. FIXED-INTERVAL SMOOTHER FOR JUMP MARKOV SYSTEMS

As aforementioned, the aim is to approximate the smoothing pdf of the jump Markov system (1–2–3–4) as a \( M \)-hypotheses Gaussian mixture according to:

\[
p(x_k|z_{1:T}) = \sum_{j \in \mathcal{M}} P(m_i^k|z_{1:T}) p(x_k|m_i^k, z_{1:T}) \approx \sum_{j \in \mathcal{M}} P(m_i^k|z_{1:T}) N(x_k; \hat{x}_i^j(k), \hat{P}_i^j(k)).
\]

For jump Markov systems, the global (hybrid) state vector \( \xi_k \) is independent of \( z_{k+1:T} \) when conditioned on \( \xi_k \) so that \( p(\xi_k|\xi_{k+1:T} = x_k, m_{k|k}, m_{k+1|k}, z_{1:T}) \) is equal to \( p(\xi_k|\xi_{k+1:T} = x_k, m_{k|k}, m_{k+1|k}, z_{1:T}) \) by marginalizing over \( m_k \). One gets the equality:

\[
p(x_k|x_{k+1}, m_{k+1|k}, z_{1:T}) = p(x_k|x_{k+1}, m_{k+1|k}, z_{1:T})
\]

which is conditioned only on the active mode over the sampling period ending at \( t_{k+1} \).

All distributions are henceforth approximated by Gaussians. From the statistics \( \{\hat{x}_i^j(k), \hat{P}_i^j(k)|k\}_{i \in \mathcal{M}} \) and \( \{\hat{x}_i^j(k), \hat{P}_i^j(k)|k\}_{i \in \mathcal{M}} \) produced by an IMM filter at times \( k = 0, \ldots, T \), together with \( \{\hat{x}_i^j(k), \hat{P}_i^j(k)|k\}_{i \in \mathcal{M}} \) produced at times \( k + 1 = 1, \ldots, T \), the proposed algorithm recursively determines the smoothing mode-conditioned densities \( p(x_k|m_i^k, z_{1:T}) \approx \mathcal{N}(x_k; \hat{x}_i^j(k), \hat{P}_i^j(k)) \) and the smoothed mode probabilities \( \{\mu_i^j(k) = P(m_i^k|z_{1:T})\}_{j \in \mathcal{M}} \) for \( k = T - 1, \ldots, 0 \).

A. Step 1 of SR3: mode-matched smoothing

**Theorem 1.** From the knowledge of \( p(x_k|m_i^k, z_{1:T}) \approx \mathcal{N}(x_k; \hat{x}_i^j(k), \hat{P}_i^j(k)) \) at time \( k + 1 \), the mean and covariance of the smoothed mixing density \( p(x_k|m_i^k, z_{1:T}) \approx \mathcal{N}(x_k; \tilde{x}_i^j(k), \tilde{P}_i^j(k)) \) are first determined with the Rauch-Tung-Striebel formulae:

\[
G_i^j = C_i^{k+1}(P_i^{k+1|k})^{-1}
\]

\[
\tilde{x}_i^j(k) = \tilde{x}_i^j(k|k-1) + C_i^{k+1}(P_i^{k+1|k})^{-1}(z_{k+1:T} - \tilde{x}_i^j(k|k-1))
\]

\[
\tilde{P}_i^j(k) = \tilde{P}_i^j(k|k) + C_i^{k+1}(P_i^{k+1|k})^{-1}C_i^{k+1}^T
\]
where
\[ C_{k|k+1} = \int (x_k - \bar{x}_{k|k}^T) f_b(x_k) - \bar{x}_{k+1|k}^T) \mathcal{N}(x_k; \bar{x}_{k|k}^T, \tilde{P}_{k|k}) dx_k. \] (12)

**Proof.** The equations (9)-(12) can be demonstrated by following exactly the proof of [24, Sec. II.A] with all densities conditioned on \( m_{k+1}^i \), and by using the property (8). An approximation of the integral (12) can be easily evaluated by means of the unscented transform, as suggested in [24]. □

In contrast to the single-model smoother, equations (9), (10), (11) do not end the recursion cycle because the smoothing density of \( x_k \) is conditioned on \( m_{k+1}^i \) instead of \( m_{k+1} \). The following interaction stage bridges the gap between the Gaussian approximations to the mode-conditioned smoothing densities \( \mathcal{N}(x_k; \bar{x}_{k|T}^M, \tilde{P}_{k|T}^M) \) and \( \mathcal{N}(x_k; \bar{x}_{k|T}^i, P_{k|T}^i) \) with \( P_{k|T}^i = p(x_k|m_{k+1}^i, z_{1:T}) \). Two options are hereafter investigated.

**B. Step 2 of SR3: a mode interaction with \( M^2 \) combinations**

Using the total probability theorem, the targeted mode-conditioned smoothing density \( p(x_k|m_{k+1}^i, z_{1:T}) \) can be expressed as a mixture of densities conditioned on the sequence of modes over two consecutive sampling periods, namely
\[ p(x_k|m_{k+1}^i, z_{1:T}) = \sum_{i \in \mathcal{M}} p(x_k|m_{k+1}^i, m_{k+1}^i, z_{1:T}) P(m_{k+1}^i|m_{k+1}^i, z_{1:T}). \] (13)

The two forthcoming theorems enable its computation.

**Theorem 2.** The first two moments of \( p(x_k|m_{k+1}^i, m_{k+1}^i, z_{1:T}) \) can be obtained by forward-time IMM filtering and backward-time Rauch-Tung-Striebel recursions as follows:
\[ \hat{x}_{k|T}^i = P_{k|T}^i \left[ (\tilde{P}_{k|T}^i)^{-1} \hat{x}_{k|T}^i - (\tilde{P}_{k|T}^i)^{-1} \hat{x}_{k|k}^i \right], \] (14)
with
\[ P_{k|T}^i = \left[ (\tilde{P}_{k|T}^i)^{-1} - (\tilde{P}_{k|T}^i)^{-1} + (P_{k|T}^i)^{-1} \right]^{-1}. \] (15)

**Proof.** Following [22], the Bayes formula and the Markov property of the mode sequence lead to
\[ p(x_k|m_{k+1}^i, m_{k+1}^i, z_{1:T}) \propto p(z_{1:T}|x_k, m_{k+1}^i) p(x_k|m_{k+1}^i, z_{1:T}). \] (16)

Similarly, the following holds
\[ \Rightarrow p(z_{1:T}|x_k, m_{k+1}^i) \propto \frac{p(x_k|m_{k+1}^i, z_{1:T})}{p(x_k|m_{k+1}^i, z_{1:T})}. \] (17)

which yields the final equality
\[ p(x_k|m_{k+1}^i, m_{k+1}^i, z_{1:T}) \propto \frac{p(x_k|m_{k+1}^i, z_{1:T})}{p(x_k|m_{k+1}^i, z_{1:T})}. \] (18)

Interestingly, Eq. (13) of the interaction step is common with [22, Eq. 73] albeit [22] evaluates the smoothed estimate \( \hat{x}_{k|T}^i \) by combining the estimates produced by a conventional IMM filter and a backward-time IMM filter restricted to linear systems with invertible state transition matrix. Moreover, this backward-time IMM filter requires to be initialized at final time \( T \) with no prior information. Note that the maximum likelihood estimate argmax \( p(z_{1:T}|x_k, m_{k+1}^i) \) writes as
\[ \hat{x}_{k|T}^i = p(x_k|m_{k+1}^i, z_{1:T})^{-1} \hat{x}_{k|T}^i \] (20)
with
\[ P_{k|T}^i = \left[ (\tilde{P}_{k|T}^i)^{-1} - (\tilde{P}_{k|T}^i)^{-1} \right]^{-1}, \] (21)
and is nothing else but the “one-step backward-time predicted estimate and error covariance” computed by the backward-time IMM filter of [22].

**Theorem 3.** The smoothed mixing probabilities \( \{ P_{k|T}^i = P(m_{k+1}^i|m_{k+1}^i, z_{1:T}) \} \forall i \in \mathcal{M} \) involved in (13) are expressed as
\[ P_{k|T}^i = \frac{p(x_k|m_{k+1}^i, m_{k+1}^i, z_{1:T})}{p(z_{1:T}|m_{k+1}^i, z_{1:T})} = \frac{\bar{p}_{ji} \Lambda_j}{d_j}, \] (22)
where the likelihood
\[ \Lambda_j = p(z_{1:T}|m_{k+1}^j, m_{k+1}^j, z_{1:T}) \] (23)
can be approximated by
\[ \Lambda_j \approx \mathcal{N}(\bar{x}_{k|T}; 0, \bar{D}_{k|T}^j), \] (24)
\[ \bar{D}_{k|T}^j = \hat{x}_{k|T}^j - \hat{x}_{k|k}^j, \] and
\[ d_j = p(z_{1:T}|m_{k+1}^j, z_{1:T}) = \sum_{i \in \mathcal{M}} \bar{p}_{ji} \Lambda_j \] (25)
stands for the normalizing constant.

**Proof.** Eq. (22) is straightforward. The approximation (24) has been proposed in [22].

The posterior mean \( \hat{x}_{k|T}^j \) and covariance \( \bar{P}_{k|T}^j \) of the mode-conditioned smoothing density (13) are eventually computed via their moment-matched approximations
\[ \hat{x}_{k|T}^j = \sum_{i \in \mathcal{M}} \bar{p}_{k+1|T}^i (\tilde{P}_{k|T}^i)^{-1} (\bar{x}_{k|T}^i - \hat{x}_{k|T}^i) \] (26)
\[ \bar{P}_{k|T}^j = \sum_{i \in \mathcal{M}} \bar{p}_{k+1|T}^i (\tilde{P}_{k|T}^i)^{-1} (\bar{x}_{k|T}^i - \hat{x}_{k|T}^i)(\bar{x}_{k|T}^i - \hat{x}_{k|T}^i)^T. \] (27)

These last equations end the smoothing recursion.

**C. Step 2 of SR3: an alternative mode interaction with \( M \) combinations**

Instead of combining the \( M^2 \) filtering densities \( p(x_k|m_{k+1}^i, z_{1:T}) \) and \( p(x_k|m_{k+1}^j, z_{1:T}) \), another option to build \( p(x_k|m_{k+1}^i, z_{1:T}) \) is to directly fuse the \( M \) filtering densities \( p(x_k|m_{k+1}^i, z_{1:T}) \) and \( p(x_k|m_{k+1}^j, z_{1:T}) \). This alternative option was pointed out in the conclusion of [22], and can be solved by the following theorem.
Theorem 4. The backward filtering density \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \) is obtained using (20)-(21). Eventually, the recursion is closed two moments of \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \) are equal to \( P(m^j_{k+1}|\bar{z}_{k+1:T}) = \mu^{(j)}_{k+1}[T] \). The corresponding first two moments of \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \) come as

\[
\bar{x}^{(j)}_{k|k+1} = \sum_{i \in \mathcal{M}} \bar{P}^{(i)}_{k|k+1} \left[ (P^{(i)}_{k+1})^{-1} x^{(j)}_{k|k+1} + (P^{(j)}_{k+1})^{-1} x^{(j)}_{k|k+1} \right], \\
\tilde{x}^{(j)}_{k|k+1} = \sum_{i \in \mathcal{M}} \tilde{P}^{(i)}_{k|k+1} \left[ (P^{(i)}_{k+1})^{-1} - (P^{(j)}_{k+1})^{-1} \right].
\]

Proof. Eq. (28) and its moment matched approximations (29)-(30) were introduced in [22] as the mixing step of a backward IMM filter. The equality \( P(m^j_{k+1}|\bar{z}_{k+1:T}) = P(m^j_{k+1}|\bar{z}_{k+1:T}) \) comes from the Markov properties of the mode sequence. □

Note that the mean \( \tilde{x}^{(j)}_{k|k+1} \) and the covariance \( \tilde{P}^{(j)}_{k|k+1} \) can be obtained using (20)-(21). Eventually, the recursion is closed with the combination of \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \) and \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \), as follows.

Theorem 5. The mean and the covariance of the smoothed density \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \) are \( \mathcal{N}(x_k;\bar{x}_{k|T},\tilde{P}_{k|T}) \).

Proof. By Bayes formula, the density \( p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \) can be rewritten as

\[
p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) \propto p(x_k|m^j_{k+1},\bar{z}_{k+1:T}) p(x_k|z_{k+1:T},m^j_{k+1}).
\]

Following a reasoning similar to proof of Theorem 2 and using the fact that the model-conditioned likelihood \( p(z_{k+1:T}|x_k,m^j_{k+1}) \) is equal to \( \mathcal{N}(x_k;\bar{x}_{k|k+1},\tilde{P}_{k|k+1}) \), (31) and (32) hold. □

D. Step 3 of SR3, smoother output and algorithm implementation

The posterior smoothed mode probability \( \mu^{j}_{k|T} \) of mode \( j \) at time \( k \) is given by

\[
\mu^{j}_{k|T} = \frac{p(z_{k+1:T}|m^j_{k+1},\bar{z}_{k+1:T}) p(m^j_{k+1})}{\sum_{j \in \mathcal{M}} p(z_{k+1:T}|m^j_{k+1},\bar{z}_{k+1:T}) p(m^j_{k+1})} = \frac{d_j \mu^{j}_{k|k}}{\sum_{j \in \mathcal{M}} d_j \mu^{j}_{k|k}},
\]

For output purposes, the overall smoothing density \( p(x_k|\bar{z}_{k+1:T}) \) can be approximated by its moment-matched Gaussian pdf \( \mathcal{N}(x_k;\bar{x}_{k|T},\tilde{P}_{k|T}) \), where

\[
\bar{x}_{k|T} = \sum_{j \in \mathcal{M}} \mu^{j}_{k|T} \bar{x}^{(j)}_{k|T}, \\
\tilde{P}_{k|T} = \sum_{j \in \mathcal{M}} \mu^{j}_{k|T} \left[ P^{(j)}_{k|T} + (\bar{x}^{(j)}_{k|T} - \bar{x}_{k|T})(\bar{x}^{(j)}_{k|T} - \bar{x}_{k|T})^T \right].
\]

For detection issues, the MAP mode estimate \( \hat{j}_k \) at time \( t_k \) writes as

\[
\hat{j}_k = \arg \max_{j=1,...,M} \mu^{j}_{k|T}.
\]
the augmented state $p(X_{k+n|n}|m^i_{k+n}, z_{1:k+1})$ is conditioned on the model $m_{k+n}$ running at $k+n$ so that the smoothed estimate of $x_k$ is also conditioned on $m_{k+n}$. A nonlinear solution is proposed in [11], where an IMM filter is based on a bank of Unscented Kalman filters (UKFs). The authors show how, thanks to the fact that the corresponding augmented state models are partially linear, the unscented transform underlying the UKF can be performed with the same reduced number of sigma points whatever the lag length $n$. A fixed-lag smoother for linear jump Markov systems using an IMM filter without state augmentation was proposed by [26] for $n = 1$ only, and by [27] for arbitrary lag lengths but under the assumption that there are no model jumps over the interval $(k,k+n)$.

In light of Section IV, the fixed-lag smoothed estimate at time $k$ can be obtained by simply applying the two-step recursion—Rauch-Tung-Striebel smoothing and mode interaction SR3—for $k+n - 1, \ldots, k$ after the IMM filtering has been performed until time $k+n$. As already stated, this approach can be considered as an independent additional processing on the real time filtered estimates and does not require any change to the existing models. The smoothed estimate at $k$ is conditioned on $m^j_k$ instead of $m^j_{k+n}$, as for the augmented state approach, and model jumps are taken into account over the interval $(k,k+n)$ through the mode interaction stage. Notice that in Algorithm 1, the smoother gain $G^i_k$, the inverses $(P^i_{k|k})^{-1}$ and $(P^i_{k|j})^{-1}$, the products $(P^i_{k|k})^{-1} (P^i_{k|j})$ and $(P^i_{k|j})^{-1} (P^i_{k|k})^{-1}$ may be precomputed and stored while performing the IMM filtering in order to get a faster implementation of the multiple-model fixed-lag smoothing recursion.

VI. SIMULATION EXAMPLES

A. Fixed-interval smoothing

A simulated 2D target tracking example is presented to examine the estimation errors and the posterior mode probabilities produced by the proposed Interactive Multiple Model...
Rauch-Tung-Striebel (IMM-RTS) smoother. In order to compare it with [22], an invertible state dynamics is considered. The system state is defined as \( x = [x, y, \dot{x}, \dot{y}]^T \) where \((x, y)\) term the Cartesian coordinates of the target and \((\dot{x} = \frac{dx}{dt}, \dot{y} = \frac{dy}{dt})\) stand for its velocities. The mode set contains two discrete-time correlated random walks: a first one with a high diffusion parameter \( D_1 = 5^2\text{m}^2\text{s}^{-3} \) (maneuvering mode 1) and a second one with a lower diffusion parameter \( D_2 = 0.5^2\text{m}^2\text{s}^{-3} \) (nearly Constant Velocity or CV mode 2). The state space equations write as
\[
\begin{align*}
    x_k &= \begin{bmatrix} 1 & 0 & \Delta t_k & 0 \\ 0 & 1 & 0 & \Delta t_k \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} x_{k-1} + q_{k-1}^j \\
    Q_{k-1}^j &= \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 2D_k \Delta t_k & 0 \\ 0 & 0 & 0 & 2D_k \Delta t_k \end{bmatrix}
\end{align*}
\]
with \( \Delta t_k = t_k - t_{k-1} \). The vector \( z_k \) gathers the noisy measured range and bearing of the target at time \( t_k \) and is sampled for \( k = 1, \ldots, T \) with period \( \Delta t_k = 5s \). Thus, the output equation common to all modes is
\[
    z_k = \begin{bmatrix} \sqrt{x_k^2 + y_k^2} \\ \arctan\left(\frac{y_k}{x_k}\right) \end{bmatrix} + r_k,
\]
with \( R_k = \text{diag}([250^2\text{m}^2, 0.02\text{rad}^2]) \).

The probability transition matrix is set to
\[
    \Pi = \begin{bmatrix} \pi_{11} & \pi_{12} \\ \pi_{21} & \pi_{22} \end{bmatrix} = \begin{bmatrix} 0.97 & 0.03 \\ 0.03 & 0.97 \end{bmatrix}.
\]

The target is tracked for 90 steps (or 450s) on a randomly generated trajectory. It evolves first according to the maneuvering mode 1, then the nearly CV mode 2 and finally the maneuvering mode 1 again. The switching times between modes occur at the deterministic values of \( k = 30 \) and \( k = 60 \). At initial time \( k = 0 \), the prior mode probabilities are assumed equal to each other and the initial position and velocity estimates of the base state \( x_0 \) are arbitrarily set to \([2000, 2000, 0, 0]^T\) with covariance \( P_{0|0} = \text{diag}([1, 1, 100, 100]) \) for all modes.

The algorithm was evaluated over 50 Monte Carlo runs. An example of trajectory is displayed in Fig. 1. Our IMM smoother is compared to the IMM/GPB\_filtering solutions [3], [28], the GPB2-RTS smoothing solution [29], the IMM-RTS smoothing solution [19] and the IMM two-filter smoothing solution [22]. The latter requires a backward-time IMM filter initialized with no prior information. As proposed by [22], the backward initialization at final time \( T \) is performed by setting for all modes the position estimate \( \hat{x}_{T|T}^b \) and associated covariance to the final measurement \( z_{T|T} \) and its covariance; the final velocity estimate \( \hat{\dot{x}}_{T|T}^b \) is set to 0 with the arbitrary large associated covariance matrix \( 10^9 I_2 \text{m}^2\text{s}^{-2} \); the modes are assumed equiprobable at the terminal time.

In Table I, the time-averaged empirical root-mean-square errors (RMSE) for the position and the velocity are shown, as well as the observed time-averaged wrong detection probability (i.e. the average probability of selecting the wrong mode with the MAP of (36)). These quantities are also displayed for each time step of the simulation in Fig. 2(a), Fig. 2(b) and Fig. 2(c) (only for the IMM-RTS smoother with Interaction 1, the GPB2-RTS smoother and the IMM two-filter smoother). The results show that our IMM-RTS smoother is well-behaved, independently of the interaction type, with a significant reduction of the RMSE errors in comparison to the filtering solutions. The detection of the active model is also more efficient. The accuracy of the smoother is similar to the two-filter smoothing solution. The GPB2-RTS smoother displays a lower performance both in terms of RMSE and wrong detection probabilities.

Fig. 2. Comparison of the IMM filter and the smoothers: (from top to bottom) (a) RMSE in Position, (b) RMSE in Velocity and (c) Mode error probability.

Concerning the respective computation times, the GPB$_2$-RTS smoother [17], [18] entails approximations which require a lower number of matrix inversions, and is faster in this example. The same holds for the IMM-RTS smoother [19], though at the expense of a lack of theoretical soundness. Nevertheless, the approach proposed in this paper involves a lower number of filters and smoothers in addition to providing improved accuracy. It is interesting when time and measurement updates are computationally expensive.

B. Fixed-lag smoothing

The evaluation of the proposed multiple-model smoother is completed by an example with nonlinear dynamics in the context of fixed-lag smoothing. The algorithm is compared in this section to the augmented state IMM smoother of [11] (“Morelande et al.”). Two discrete-time coordinated turn (CT) models with unknown turn rates $\omega$, with $j = 1, 2$, are considered. The target evolves in 2D and the state vector is now $x = [x, \dot{x}, y, \dot{y}, \omega]^T$. The discrete-time dynamics of the CT models [30] is given by

$$x_k = \begin{pmatrix} 1 & 1 & 0 & 0 & 0 \\ -\cos \omega_k & 0 & 0 & -\sin \omega_k & 0 \\ 0 & \cos \omega_k & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} x_{k-1} + \begin{pmatrix} q_k^1 \\ q_k^2 \\ q_k^3 \end{pmatrix}$$

where $Q_k = \begin{pmatrix} \sigma_{x,j}^2, \sigma_{y,j}^2, M, \sigma_{\omega,j}^2 \end{pmatrix}$ and $M = \begin{pmatrix} \Delta t^{3/2} \Delta t^{1/2} \\ \Delta t^{1/2} \Delta t \end{pmatrix}$. For the first mode, we set $\sigma_{x,1}^2 = 1$, $\sigma_{y,1}^2 = 1$, $\sigma_{\omega,1}^2 = 0$ (constant turn rate and nearly constant velocity mode 1) and, for the second mode, $\sigma_{x,2}^2 = 100$, $\sigma_{y,2}^2 = 100$, $\sigma_{\omega,2}^2 = 1.75 \times 10^{-3}$ (maneuvering mode 2). The output equation is given by

$$z_k = \begin{pmatrix} 1 & 0 & 0 & 0 \end{pmatrix} x_k + r_k$$

and the probability transition matrix is identical to (40).

As previously, the trajectory and measurements are randomly generated. The target is observed for 90 steps with a sampling period of $\Delta t = 1$s for all $k$. The initial state value is $x_{0|0} = [0, 30, 0, 30, 0.05]^T$ with $P_{0|0} = \text{diag}([10, 1, 10, 1, 0.001])$ for all modes. The switching times are set to $k = 30$ and $k = 60$. The maneuvering model is running between $k = 30$ and $k = 60$. The constant turn and velocity model is active before $k = 30$ and after $k = 60$. Fig. 3 gives a trajectory sample. Comparisons between the methods are performed over
50 Monte Carlo runs. The time averaged empirical root-mean-
squared errors are plotted as a function of the time lag for the
position, the velocity and the turn rate in Fig. 4(a), Fig. 4(b)
and Fig. 4(c) respectively. The observed time averaged wrong
mode detection probability is displayed in Fig. 4(d). Regarding

\[ (p_{k+1}^{-1}) \]

the RMSE, the IMM-RTS and Morelande’s smoothers display
a similar accuracy whatever the time lag. Besides, the wrong
mode detection probabilities are higher with the IMM-RTS
smoother for time lags 1 and 2. This pitfall arises from the
impossibility to compute the smoothed mode probabilities
until \( (p_{k+1}^{-1}) \) is invertible. After that, the smoothed probabilities
can be conveniently evaluated, and the IMM-RTS smoother
reaches a slightly better detection rate of the active mode than
Morelande’s algorithm. The IMM-RTS smoother is faster in
this example than the augmented-state implementation.

VII. CONCLUSION AND PROSPECTS

This paper investigated a suboptimal fixed-interval smoothing
algorithm based on a forward-time IMM filtering and a
backward-time recursive process. Each recursion consists of
a smoothing step and involves Rauch-Tung-Striebel equations
adapted to jump Markov systems together with a specific in-
teraction step to allow mode cooperation. The first smoothing
stage runs only \( M \) Rauch-Tung-Striebel smoothers in parallel,
each one being conditioned on one of the \( M \) possibly active
modes within the sampling period \( (t_k, t_{k+1}) \). Its results are then
combined with interactions related to the \( M^2 \) admissible pairs
of models over the successive sampling periods \( (t_k-1, t_k) \) and
\( (t_k, t_{k+1}) \). Two complementary combination types are investi-
gated, the second one being computationally cheaper. The re-
cursions SR3 introduced above are not approximations: Step 1
is derived without approximations (end of Section III-B), the
exact equation for Step 2 is (14) and Step 3 comes from
(33). Approximations are only done when deriving a tractable
solution by assuming that the pdf is Gaussian. In contrast,
SR1 and SR2 consider approximations both in the recursion
cycle and for the shape of the pdf. An example of tracking
of a maneuvering target shows that the proposed smoother
performs significantly better than the IMM filter [3], the GPB2-
RTS smoother [29], the IMM-RTS smoother [19] and equally
well as the two-filter based scheme [22]. Unlike the latter,
the proposed algorithm is suited to nonlinear dynamics and
measurement equations. In the context of fixed-lag smoothing,
comparisons with the solution of [11] displayed a similar
accuracy and a better detection of the active mode for a
sufficiently large time lag.

Future work will concentrate on adapting the proposed ap-
proach to a bank of heterogeneous-order models, i.e. to models
which share only parts of their respective state vectors [9][10].
