ENSEMBLE APPROXIMATIONS FOR CONSTRAINED DYNAMICAL SYSTEMS USING LIOUVILLE EQUATION

MARIANNE SOUAIBY, ANEEL TANWANI, AND DIDIER HENRION

Abstract. For a class of state-constrained dynamical systems described by evolution variational inequalities, we study the time evolution of a probability measure which describes the distribution of the state over a set. In contrast to smooth ordinary differential equations, where the evolution of this probability measure is described by the Liouville equations, the flow map associated with the nonsmooth differential inclusion is not necessarily invertible and one cannot directly derive a continuity equation to describe the evolution of the distribution of states. Instead, we consider Lipschitz approximation of our original nonsmooth system and construct a sequence of measures obtained from Liouville equations corresponding to these approximations. This sequence of measures converges in weak-star topology to the measure describing the evolution of the distribution of states for the original nonsmooth system. This allows us to approximate numerically the evolution of moments (up to some finite order) for our original nonsmooth system, using a solver that uses finite order moment approximations of the Liouville equation. Our approach is illustrated with the help of an academic example.

1. Introduction

In the theory of dynamical systems, studying the evolution of state trajectories, both qualitatively and quantitatively, is a common occurrence. For ordinary differential equations, with a *fixed* initial condition described by a point in the finite-dimensional vector space, the tools for analyzing the behavior of trajectories are widely available. However, for many applications, it is of interest to consider the evolution of dynamical systems when the initial condition is described by a distribution over some set in the state space. This article explores this latter direction for a particular class of nonsmooth dynamical systems.

If we consider a probability measure to describe the distribution of the initial conditions of a dynamical system, then the time evolution of this initial probability measure with respect to underlying dynamics is the object of our interest. For an autonomous dynamical system described by an ordinary differential equation (ODE) with Lipschitz continuous vector field, the time evolution of this measure is described by a linear partial differential equation (PDE) called the *Liouville equation* or the continuity equation, see e.g. [40, Section 5.4]. The solution to the Liouville equation, that is the probability measure describing the distribution at time t, is the pushforward or image measure of the initial probability measure through the flow map at time t. Lipschitz continuity of the vector field ensures that the flow map of the ODE is invertible, which in turn ensures that the pushforward measure is the unique solution to the Liouville equation. This approach of associating the continuity equation with finite dimensional ODEs has found relevance in numerical optimal control [31, 26] as well as in several control-theoretic problems [4, 11, 12].

This work was supported by the ANR project ConVan with grant number ANR-17-CE40-0019-01.

When the vector field is not Lipschitz continuous, then the study of the evolution of the initial distribution is more involved. The first occurrence of continuity equations corresponding to nonsmooth ODEs occurs in [22]. Continuity equations corresponding to one-sided Lipschitz vector fields have been studied in [9, 10]. In [2], the authors consider less regular ODEs and study uniqueness of solutions for (Lebesgue) almost-all initial conditions by using the Liouville equation.

The dynamical systems for which we want to study the evolution of probability measures (describing the distribution of states) are the so-called *constrained systems* described by differential inclusions. In particular, given a closed convex set $S \subset \mathbb{R}^n$, and a continuously differentiable function $f : \mathbb{R}^n \to \mathbb{R}^n$, we describe the evolution of constrained systems via the differential inclusion

$$\dot{x} \in f(x) - \mathcal{N}_S(x) \tag{1}$$

where $\mathcal{N}_S(x) \in \mathbb{R}^n$ denotes the outward normal cone to the set S at the point $x \in \mathbb{R}^n$. Since the normal cone takes a zero value in the interior of S, it is clear that the right-hand side of (1) is potentially discontinuous at the boundary of the set S. One can also think of (1) as an evolution variational inequality, described as

$$\langle \dot{x}(t) - f(x(t)), y - x(t) \rangle \geqslant 0,$$

for all $y \in S$, $x(t) \in S$, $t \in [0, T]$. Such dynamical systems have been a matter of extensive study in past decades due to their relevance in engineering and physical systems. A recent survey article [13], and a research monograph [1], provide an overview of different research oriented directions in the literature pertaining to system (1) and its connections to different classes of nonsmooth mathematical models. Analysis of such systems requires tools from variational analysis, nonsmooth analysis, set-valued analysis [3, 34, 37]. Results based on stability analysis with computational aspects have been addressed recently by the authors in [38].

For a fixed initial condition, $x(0) \in S$, the question of existence and uniqueness of solution to system (1) has already been well-established in the literature, and the origins of such works can be found in [35], see [23] for a recent exposition. However, if we consider the initial conditions described by a probability measure, then the evolution of this measure under the dynamics of (1) has received very little attention in the literature. One can study such problems by considering stochastic versions of (1) by adding a diffusion term on the right-hand side. Such systems first came up in the study of variational inequalities arising in stochastic control [5], and in the literature, we can find results on existence and uniqueness of solutions in appropriate function space. In [18], this is done by considering Yosida approximations of the maximal monotone operator, whereas [6] provides a proof based on time-discretization of system (1). These approaches have been generalized for prox-regular set S in [7], and the case where the drift term contains Young measures [16, 17]. One could also, in principle, formulate a partial differential equation with set-valued elements and study the solutions of such equations under appropriate hypothesis, which is the case in [8] but it is not clear how to derive the corresponding set-valued partial differential equation for system (1) and whether the resulting inclusion would satisfy the necessary hypothesis for well-posedness. Different from these approaches, and inspired by the fact that the evolution of a probability measure for single-valued dynamical system is described by Liouville equation, it is natural to ask whether the evolution of a probability measure under the dynamics of system (1) can be studied using Liouville equation. To the best of authors' knowledge, this approach has only been adopted in [21], where the authors consider system of form (1) without the drift term $f(\cdot)$. Since the right-hand side of (1) is set-valued, it is not immediately clear how the divergence term in the Liouville equation is to be interpreted. In [21], the authors consider approximations

to the solutions of Liouville equation associated with (1), which are similar to time-stepping algorithm. That is, a time-discretization technique is introduced which is based on projecting the density function on to the constraint set with respect to Wasserstein metric.

In this paper, we consider a different route for computing the approximate solution of system (1) in the space of probability measures. Inspired by the concepts presented in [2], our basic idea is to consider Lipschitz approximations of system (1). The particular approximations that we work with are the ones obtained by *Yosida-Moreau* regularization and are parameterized by a positive scalar converging to zero. We can then associate a single-valued Liouville equation to each of these approximants, and establish convergence of the resulting sequence of measures. Unlike [21], our approach for numerically solving the Liouville equation does not depend upon discretization in time, or space for that matter. Instead, we use functional discretization: we choose a family of test functions (the monomials) on which the evolution measure and the associated moments are then approximated numerically by a hierarchy of semidefinite programs. Furthermore, we also show that the support of the sequence of measures converges (with respect to the Hausdorff distance) to the support of the pushforward measure for the nonsmooth system. These analytical results allow us to get an approximation of the actual solution.

Since the pushforward measure, at each time instant, is an infinite-dimensional object, it can be challenging to approximate it numerically. One possibility – that we do not explore here – could to use Monte-Carlo probabilistic algorithms. Instead, we investigate a purely deterministic approach: in order to get a quantitative measure of the distribution of state at any time instant, which involves building a hierarchy of moments defined by the action of a finite Borel measure on polynomial test functions, and encoding the positivity constraints on moment matrix by using sum-of-squares (SOS) decomposition. This technique, called moment-SOS hierarchy [27] has been used in several engineering problems, and for our purposes, it allows us to approximate numerically the moments (up to some finite order) associated with the pushforward measure. Also, using the recent developments on approximating the support of a measure with the Christoffel-Darboux kernel [30], we can approximate the support of the pushforward measure, and hence the trajectories corresponding to a certain initial distribution.

The remainder of the article is organized as follows: In Section 2, we formalize the problem and introduce the basic mathematical elements necessary for doing so. In Section 3, we construct Lipschitz approximations of our initial dynamical system. In Sections 4 and 5, we study certain properties of the sequence of measures associated with approximations constructed in Section 3. Numerical aspects for approximating the moments, and support, of the probability measure describing the evolution of system dynamics are also discussed in Sections 4 and 5. We illustrate our results with the help of an academic example in Section 6. Some concluding remarks with possible future directions appear in Section 7, followed by an Appendix which collects some additional tools used in the development of our results.

2. Preliminaries and Problem formulation

2.1. **Evolution of ensembles.** Let us consider the time-varying ODE

$$\dot{z}(t) = g(t, z(t)), \quad z(0) = z_0, \tag{2}$$

over a given time interval $[0, T]$, where $g : [0, T] \times \mathbb{R}^n \to \mathbb{R}^n$ is a given vector field and $z(t) \in \mathbb{R}^n$ is the state. For each $t \in [0, T]$, let us consider the flow map $G_t : \mathbb{R}^n \to \mathbb{R}^n$, so that the mapping $z_0 \mapsto G_t(z_0)$ provides the value of state

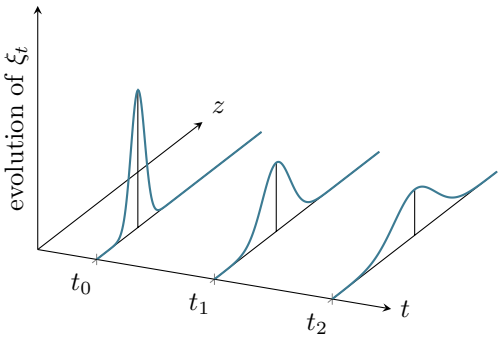

FIGURE 1. Evolution of probability measure ξ_t w.r.t. time and space.

trajectory of (2) at time t, and moreover it satisfies

$$\partial_t G_t(z_0) = g(t, G_t(z_0)), \;\; G_0(z_0) = z_0, \;\; (t, z_0) \in [0, T] \times \mathbb{R}^n. \tag{3}$$

In this article, we consider the evolution of dynamical systems when the initial condition is defined probabilistically. In particular, we use the notation $z(0) \sim \xi_0$ to mean that $z(0)$ is a random variable whose law is a given probability measure, or density function $\xi_0 \in \mathcal{P}(\mathbb{R}^n)$, where $\mathcal{P}(S)$ denotes the set of probability measures supported on S.

This model allows to capture an initial spatial distribution of particles. To define the corresponding density function at time $t \geqslant 0$, denoted by $\xi_t \in \mathcal{P}(\mathbb{R}^n)$, we consider the pushforward or image measure of ξ_0 through the flow map $G_t(\cdot)$. That is, let

$$\xi_t := G_t \sharp \xi_0, \tag{4}$$

so that, for every Borel subset $B \subset \mathbb{R}^n$, it holds that

$$\xi_t(B) = \xi_0(G_t^{-1}(B)) = \xi_0(\{z \in \mathbb{R}^n : G_t(z) \in B\}).$$

The evolution of ξ_t is described by the following PDE, called the continuity or *Liouville* equation:

$$\partial_t \xi_t + \operatorname{div}(\xi_t g) = 0, \tag{5}$$

with the initial condition:

$$\xi|_{t=0} = \xi_0. \tag{6}$$

The Liouville equation (5) should be understood in the sense of distributions, i.e.

$$\int_{\mathbb{R}^n} (\partial_t v(t, z) + \partial_z v(t, z) \cdot g(t, z)) \, d\xi_t(z) = 0$$

for all continuously differentiable functions v from $\mathbb{R}_+ \times \mathbb{R}^n$ to $\mathbb{R}$. The equivalence between the solutions of ODE (2) and PDE (5), is established in the following result, see e.g. [40, Theorem 5.34]:

Theorem 1. *For each $t \in [0, T]$, let $G_t : \mathbb{R}^n \to \mathbb{R}^n$ be a diffeomorphism so that (3) holds. Given $\xi_0 \in \mathcal{P}(\mathbb{R}^n)$, let ξ_t be defined as in (4). Then, ξ_t is the unique solution of the Liouville equation (5)-(6) over the time interval $[0, T]$.*

The importance of the *Liouville* PDE relies on its linearity in the probability measure ξ_t, whereas the *Cauchy* ODE is nonlinear in the state trajectory $z(t)$. This PDE governs the time evolution of a measure transported by the flow of a nonlinear dynamical system. The nonlinear dynamics is then replaced by a linear equation on measures. It is important to note that, in Theorem 1, the equivalence

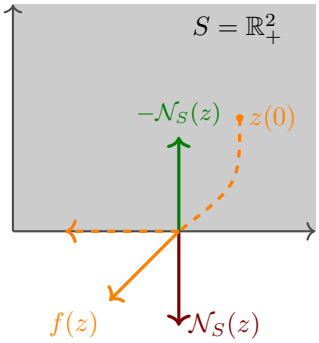

FIGURE 2. State trajectories in constrained system with $S = \mathbb{R}^n_+$.

is established under the assumption that G_t is a diffeomorphism for each $t \in [0, T]$, which in particular requires that the flow map G_t is invertible. ODEs with Lipschitz vector fields have this property, but when the vector field is not Lipschitz continuous in state variable, the backward invertibility assumption may not hold, or the flow map G_t may itself not be uniquely defined.

2.2. **Ensembles of constrained system.** In this paper, we are interested in studying a class of dynamical systems described by the variational inequalities

$$\dot{z}(t) \in f(t, z(t)) - \mathcal{N}_{S(t)}(z(t)), \quad z(0) \sim \xi_0, \tag{7}$$

over an interval $[0, T]$ for some given $T > 0$, where $f : [0, T] \times \mathbb{R}^n \to \mathbb{R}^n$ is a given vector field, $S : [0, T] \rightrightarrows \mathbb{R}^n$ a compact and convex-valued mapping, and we recall that the normal cone to S at z is defined by

$$\mathcal{N}_S(z) := \{\lambda \in \mathbb{R}^n \mid \langle \lambda, z' - z \rangle \leqslant 0, \forall z' \in S\}. \tag{8}$$

If $z \in \mathrm{int}(S)$, the interior of S, then $\mathcal{N}_S(z) = 0$ and by convention, we let $\mathcal{N}_S(z) := \emptyset$ for all $z \notin S$. The formalism of system (7) with inclusion naturally allows us to describe dynamics constrained to evolve in set S. Using the depiction in Figure 2, it is seen that, during the evolution of a trajectory, if $z(t)$ is in interior of S, then $\mathcal{N}_S(z(t)) = 0$ and the motion of the trajectory continues according to the differential equation $\dot{z}(t) = f(t, z(t))$. Whenever $z(t)$ is on the boundary, we add a vector from the set $-\mathcal{N}_S(z(t))$, which restricts the motion of the state trajectory in tangential direction on the boundary of the constraint set S.

We emphasize that, in (7), $\xi_0 \in \mathcal{P}(S(0))$ is a probability measure that specifies the distribution of the initial state. For each $t \in [0, T]$, let us denote the flow map by $F_t : S(t) \to S(t)$, so that $z_0 \mapsto F_t(z_0)$ is the value at time t of the state trajectory of (7) with $z(0) = z_0$. Given this random initial condition, the state at each time t can also be interpreted as a random variable in $S(t)$, i.e. $z(t) \sim \xi_t \in \mathcal{P}(S(t))$ defined by $\xi_t := F_t \sharp \xi_0$. However, unlike Lipschitz continuous ODEs, the mapping F_t is not invertible in general. An example illustrating this fact is given next.

Example 1 (Flow map not invertible)**.** Let $f(z) = Az$ with $A = \left[\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right]$ and $S = \mathbb{R}^2_+$ and let z_0 be a given initial condition, with angle θ_0. For $t \leqslant \theta_0$, we have $z(t) = F_t(z_0) = e^{At} z_0 = \left[\begin{smallmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{smallmatrix}\right] z_0$. And for $t \geqslant \theta_0$, we have $z(t) = [|z_0| \; 0]^\top$. For example if $z_0 = [1 \; 1]^\top$, it holds $\theta_0 = \frac{\pi}{4}$ and then for $t \geqslant \theta_0$, we have $z(t) =$

$\begin{bmatrix} \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} \\ -\frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} = [\sqrt{2}\ 0]^\top$. The flow map reads

$$z(t) = F_t(z_0) = \begin{cases} e^{At} z_0 & \text{if } t \leqslant \theta_0 \\ [|z_0|\ 0]^\top & \text{if } t \geqslant \theta_0. \end{cases}$$

Indeed, as we can observe, the flow map is not invertible since given a state $z(t)$ for a given time $t \geqslant \theta_0$, it is not possible to retrieve the initial condition z_0.

As a consequence of Example 1, it is seen that the flow map associated with dynamical system (7) is not necessarily invertible, and hence the conditions of Theorem 1 are not satisfied in general for such systems. On the other hand, for each $t \in [0, T]$, the forward flow map F_t is well-defined and therefore the solution $\xi_t := F_t \sharp \xi_0$ exists and is uniquely defined. However, it is not possible to write down the evolution equation for ξ_t, like Liouville equation for smooth ODEs, due to nonsmooth set-valued dynamics in (7). Recent literature in this direction deals with such problems, either by studying partial differential equations with set-valued mappings [8] or by introducing an approximation based on time discretization [21]. In this article, our goal is to find alternate methods based on functional discretization with monomial basis to approximate the measure ξ_t and propose computational algorithms to calculate such approximations numerically.

2.3. **Problem Formulation.** We consider the dynamical system (7) with flow map $F_t : \mathbb{R}^n \to \mathbb{R}^n$. For a given $\xi_0 \in \mathcal{P}(S(0))$, since there is no direct derivation of the PDE for characterizing the evolution of $\xi_t := F_t \sharp \xi_0$, we compute an approximation of ξ_t as follows:

- Construct a sequence of ODEs with Lipschitz continuous right-hand sides which approximate the solution of ODE (7) for a fixed initial condition. This construction is based on a regularization of (7), and results in a sequence parameterized by a scalar $\lambda > 0$.
- Exploit the regularity of the approximating ODE to construct a sequence of measures $\xi_t^\lambda := F_t^\lambda \sharp \xi_0$.
- When λ tends to 0, prove that ξ_t^λ converges to $\xi_t := F_t \sharp \xi_0$ in the weak-star topology. In particular, all finite order moments of ξ_t^λ converge to the moments of ξ_t.
- When λ tends to 0, prove the convergence of the support of ξ_t^λ to the support of ξ_t in the Hausdorff metric.

From a computational viewpoint, the by-product of the above results is that, for a fixed $\lambda > 0$, one can invoke efficient numerical methods for computing moments associated with the probability measure ξ_t^λ and the support of ξ_t^λ. This allows us to compute an approximation of the moments and support of ξ_t associated with nonsmooth system (7).

3. Lipschitz Approximation

The first step in our analysis is to compute an approximation of the solutions of (7) by using Moreau-Yosida regularization. The development carried out here is inspired by [13]. We introduce a sequence of approximate solutions, the so-called Moreau-Yosida approximants $\{z_\lambda\}_{\lambda>0}$, which are obtained by solving the following ODE parameterized by $\lambda > 0$:

$$\dot{z}_\lambda(t) = f(t, z_\lambda(t)) - \frac{1}{\lambda}(z_\lambda(t) - \text{proj}(z_\lambda(t), S(t))), \quad z_\lambda(0) = z_0 \in S(0) \tag{9}$$

over the interval $[0, T]$, where $\text{proj}(z, S)$ is the (unique) Euclidean projection of vector z onto convex set S. It is observed that, for each $\lambda > 0$, the right-hand side of (9) is (globally) Lipschitz continuous, and therefore, there exists a continuously

differentiable trajectory $z_\lambda : [0,T] \to \mathbb{R}^n$ such that (9) holds for every $t \in [0,T]$. The relation between the solution of the inclusion (7) and the approximants $\{z_\lambda\}_{\lambda>0}$ holds under the following assumptions:

Assumption 1. There exists a constant $L_f > 0$ such that, for each $t \in [0,T]$,

$$|f(t,z)| \leqslant L_f(1+|z|), \quad \forall z \in \mathbb{R}^n$$
$$|f(t,z_1) - f(t,z_2)| \leqslant L_f|z_1 - z_2|, \quad \forall z_1, z_2 \in \mathbb{R}^n.$$

Assumption 2. The mapping $S : [0,T] \rightrightarrows \mathbb{R}^n$ is closed and convex-valued for each $t \in [0,T]$, and $S(\cdot)$ varies in a Lipschitz continuous manner with time, that is, there exists a constant $L_S \geqslant 0$, such that

$$d_H(S(t_1), S(t_2)) \leqslant L_S|t_1 - t_2|, \quad \forall t_1, t_2 \in [0,T].$$

The notation $d_H(A,B)$ means the Hausdorff distance between sets A and B, that is,

$$d_H(A,B) := \max\left\{\sup_{y\in A} d(y,B),\ \sup_{x\in B} d(x,A)\right\} \tag{10}$$

where $d(x,A)$ denotes the Euclidean distance between vector x and set A.

Theorem 2. *Under Assumptions 1–2, consider the sequence of solutions $\{z_\lambda\}_{\lambda>0}$ to parameterized ODE (9) on an interval $[0,T]$. Then, as $\lambda \to 0$, the sequence converges uniformly to a Lipschitz continuous function $z : [0,T] \to \mathbb{R}^n$, the unique solution to the differential inclusion (7).*

The proof of this theorem is described in the remainder of this section. Certain calculations, leading to the intermediate lemmas used in the proof, have been included in the appendix.

Proof. The basic idea of the proof is to show that the sequence $\{z_\lambda\}_{\lambda>0}$ satisfies bounds ensuring uniform convergence to a function $z(\cdot)$ solving (7). This development is carried out in four steps.

Step 1: Estimates on the sequence $\{z_\lambda\}_{\lambda>0}$. As a first step, to obtain bounds on the norm of $z_\lambda(.)$, let us begin by computing bounds on the norm of $\dot{z}_\lambda(\cdot)$ as stated in the following lemma, whose proof is relegated to Appendix A.

Lemma 3. *For each $\lambda > 0$, it holds*

$$|\dot{z}_\lambda(t)| \leqslant 2L_f + L_f|z_\lambda(t)| + L_f \max_{0\leqslant s\leqslant t} |z_\lambda(s)| + L_S, \tag{11}$$

where L_f, L_S were introduced in Assumptions 1 and 2 respectively.

Based on Lemma 3, let us now calculate $\frac{d}{dt}|z_\lambda(t)|^2$ for getting an estimate on $|z_\lambda(\cdot)|$. First, we observe that

$$\frac{d}{dt}|z_\lambda(t)|^2 = 2\langle z_\lambda(t), \dot{z}_\lambda(t)\rangle \leqslant 2|z_\lambda(t)||\dot{z}_\lambda(t)|. \tag{12}$$

Substituting (11) in (12) yields

$$\frac{d}{dt}|z_\lambda(t)|^2 \leqslant 2L_f|z_\lambda(t)|^2 + 2L_f|z_\lambda(t)|. \max_{0\leqslant s\leqslant t} |z_\lambda(s)| + (4L_f + 2L_S)|z_\lambda(t)|.$$

Let $y_\lambda(t) = |z_\lambda(t)|^2$, so

$$\frac{d}{dt}y_\lambda(t) \leqslant 2L_f y_\lambda(t) + 2L_f\sqrt{y_\lambda(t)}. \max_{0\leqslant s\leqslant t} \sqrt{y_\lambda(s)} + (4L_f + 2L_S)\sqrt{y_\lambda(t)}.$$

Since the right-hand side of this differential inequality results in a nonnegative and nondecreasing function, it follows that $y_\lambda(t) \leqslant \widehat{y}_\lambda(t)$, for all $t \in [0,T]$, where $\widehat{y}_\lambda$ satisfies

$$\begin{aligned}\frac{d}{dt}\widehat{y}_\lambda(t) &= 2L_f\widehat{y}_\lambda(t) + 2L_f\sqrt{\widehat{y}_\lambda(t)}.\sqrt{\widehat{y}_\lambda(t)} + (4L_f + 2L_S)\sqrt{\widehat{y}_\lambda(t)} \\ &= 4L_f\widehat{y}_\lambda(t) + (4L_f + 2L_S)\sqrt{\widehat{y}_\lambda(t)}. \end{aligned} \tag{13}$$

By using the substitution $v(t) = (\widehat{y}_\lambda(t))^{\frac{1}{2}}$ in (13), it yields

$$\dot{v}(t) = 2L_f v(t) + 2L_f + L_S.$$

The solution of this differential equation is $v(t) = e^{2L_f t}v(0) + (e^{2L_f t} - 1)\frac{(2L_f+L_S)}{2L_f}$. Consequently, $|z_\lambda(t)|^2 = y_\lambda(t) \leqslant \widehat{y}_\lambda(t) = v(t)^2$, and we obtain

$$|z_\lambda(t)| \leqslant e^{2L_f T}|z_\lambda(0)| + (e^{2L_f T} - 1)\frac{(2L_f + L_S)}{2L_f}, \tag{14}$$

so that $|z_\lambda(t)|$ is bounded on the interval $[0,T]$, independently of λ.

Step 2: Extracting a converging subsequence. Based on the estimates in *Step 1*, there exists a subsequence of $z_\lambda(\cdot)$ which converges to $z(\cdot)$. More formally, the following statement is obtained.

Lemma 4. *There exists a subsequence $\{z_{\lambda_i}\}_{i\in\mathbb{N}}$ which converges uniformly to a Lipschitz continuous function $z(\cdot)$ on $[0,T]$.*

The proof of Lemma 4 is a consequence of the Arzelà-Ascoli theorem since the sequence $\{z_{\lambda_i}\}_{i\in\mathbb{N}}$ is continuously differentiable and $\{\dot{z}_{\lambda_i}\}_{i\in\mathbb{N}}$ is uniformly bounded. The limit function $z(\cdot)$ is also Lipschitz continuous in this case.

Step 3: Limit is a solution. To finish the proof of Theorem 2, we just need to show that the limit $z(\cdot)$ satisfies the differential inclusion (7). This particular step requires a variational inequality, which is stated in the following lemma, and its proof is given in Appendix A.

Lemma 5. *If $\varphi : [0,T] \to \mathbb{R}^n$ is a continuous function that satisfies $\varphi(s) + \int_{t_1}^{s} f(r, z_\lambda(r))\ dr \in S(s)$ for each $s \in [t_1,t_2]$, for $t_1, t_2 \in [0,T]$, then*

$$\int_{t_1}^{t_2} \big\langle \varphi(s), \dot{z}(s) - f(s,z(s))\big\rangle\ ds \geqslant \frac{1}{2}\left(\left\|z(t_2) - \int_{t_1}^{t_2} f(r,z(r))\ dr\right\|^2 - \|z(t_1)\|^2\right). \tag{15}$$

We now complete the proof of Theorem 2 by showing that the limit of the converging subsequence $z(\cdot)$ satisfies $\dot{z}(t) \in f(t,z(t)) - \mathcal{N}_{S(t)}(z(t))$ that is, $\langle \xi - z(t), \dot{z}(t) - f(t,z(t))\rangle \geqslant 0$, for any $\xi \in S(t)$ and for almost every $t \geqslant 0$. This is indeed the case, since for every $\xi \in S(t)$, we can take a Lipschitz continuous function $\varphi : [t,T] \to \mathbb{R}^n$ such that, due to Lemma 5, we get

$$\int_{[t,t+\epsilon[} \langle \varphi(s), \dot{z}(s) - f(s,z(s))\rangle\ ds \geqslant \frac{1}{2}\left(\|z(t+\epsilon) - \int_t^{t+\epsilon} f(r,z(r))\ dr\|^2 - \|z(t)\|^2\right),$$

and by letting $\varphi(s) = \xi - (\xi - \varphi(s))$, we obtain

$$\begin{aligned}&\int_{[t,t+\epsilon[} \langle \xi, \dot{z}(s) - f(s,z(s))\rangle\ ds - \int_{[t,t+\epsilon[} \langle \xi - \varphi(s), \dot{z}(s) - f(s,z(s))\rangle\ ds \\ &\geqslant \frac{1}{2}\big\langle z(t+\epsilon) - \int_t^{t+\epsilon} f(r,z(r))\ dr + z(t), z(t+\epsilon) - \int_t^{t+\epsilon} f(r,z(r))\ dr - z(t)\big\rangle,\end{aligned}$$

which implies

$$\big\langle \xi, z(t+\epsilon) - z(t) - \int_t^{t+\epsilon} f(s,z(s))\ ds\big\rangle - \int_t^{t+\epsilon} \langle \xi - \varphi(s), \dot{z}(s) - f(s,z(s))\rangle\ ds$$

$$\geqslant \frac{1}{2}\big\langle z(t+\epsilon) - \int_t^{t+\epsilon} f(r, z(r))\ dr + z(t), z(t+\epsilon) - \int_t^{t+\epsilon} f(r, z(r))\ dr - z(t)\big\rangle.$$

From this, we get

$$\begin{aligned}
&\Big\langle \xi - \frac{1}{2}\left(z(t+\epsilon) - \int_t^{t+\epsilon} f(r, z(r))\ dr + z(t)\right), z(t+\epsilon) - z(t) - \int_t^{t+\epsilon} f(s, z(s))\ ds\Big\rangle \\
&\geqslant \int_t^{t+\epsilon} \langle \xi - \varphi(s), \dot{z}(s) - f(s, z(s))\rangle\ ds \\
&\geqslant -\epsilon \max_{s\in[t,t+\epsilon[} |\xi - \varphi(s)||\dot{z}(s) - f(s, z(s))| \\
&\geqslant -\epsilon \max_{s\in[t,t+\epsilon[} |\xi - \varphi(s)||\dot{z}(s)| - \epsilon\, L_f \max_{s\in[t,t+\epsilon[} |\xi - \varphi(s)|(1 + |z(s)|).
\end{aligned}$$

Since $z(\cdot)$ is Lipschitz continuous, $z(\cdot)$ is bounded on $[0, T]$ and differentiable almost everywhere on $[0, T]$. Hence, for almost every $t \in [0, T]$, where $z(\cdot)$ is differentiable, dividing the last inequality by ϵ, we get

$$\begin{aligned}
&\left\langle \xi - \frac{1}{2}\left(z(t+\epsilon) - \int_t^{t+\epsilon} f(r, z(r))\ dr + z(t)\right), \frac{z(t+\epsilon) - z(t)}{\epsilon} - \frac{\int_t^{t+\epsilon} f(s, z(s))\ ds}{\epsilon}\right\rangle \\
&\geqslant -M \max_{s\in[t,t+\epsilon[} |\xi - \varphi(s)| - ML_f \max_{s\in[t,t+\epsilon[} |\xi - \varphi(s)|,
\end{aligned}$$

for some constant $M > 0$. Letting ϵ tend to zero, we get

$$\langle \xi - z(t), \dot{z}(t) - f(t, z(t))\rangle \geqslant 0, \ \text{ for each } \ \xi \in S(t),$$

and hence, $z(\cdot)$ satisfies the differential inclusion (7). □

Remark 6. In the literature, we can find several proofs of convergence of solutions obtained from Moreau-Yosida regularization to the solution of systems closely related to (7), see for example [13, 29, 36]. The proof technique adopted here closely follows the outline given in [13], but the difference here is that we add the Lipschitz perturbation $f(t, z)$ on the right-hand side of (7), which modifies certain calculations.

4. Convergence of Measures

Using the results from the previous section on the convergence of solutions for fixed initial condition, we now study the evolution of probability measures for system (7). As before, let us assume that $z(0)$ is a random variable whose law is a given probability measure $\xi_0 \in \mathcal{P}(S(0))$. We recall that the flow map for system (7) is denoted by F_t, so that $t \mapsto z(t) := F_t(z_0)$ is the unique solution to (7).

For the Lipschitz approximation given in (9), consider the map $F_t^\lambda : \mathbb{R}^n \to \mathbb{R}^n$, so that $t \mapsto z_\lambda(t) := F_t^\lambda(z_0)$ defines the unique solution to (9). Since the right-hand side of (9) is Lipschitz continuous for each $\lambda > 0$, we can consider a sequence of probability measures $\xi_t^\lambda \in \mathcal{P}(S(t))$ defined as

$$\xi_t^\lambda := F_t^\lambda \sharp \xi_0$$

for each $t \in [0, T]$ and $\lambda > 0$. From Theorem 1, it follows that ξ_t^λ satisfies the partial differential equation:

$$\partial_t \xi_t^\lambda + \operatorname{div}(\xi_t^\lambda f_t^\lambda) = 0 \tag{16}$$

in the sense of distributions, with the initial condition $\xi\big|_{t=0} = \xi_0$, and

$$f_t^\lambda(z) := f(t, z) - \frac{1}{\lambda}\Big(z - \operatorname{proj}(z, S(t))\Big). \tag{17}$$

On the other hand, we do not know how to derive a meaningful PDE for ξ_t. However, in the sequel, we show that the probability measure ξ_t can be approximated

by ξ_t^λ as $\lambda \to 0$. This way, a good numerical approximation of ξ_t^λ would also provide an approximation of ξ_t.

4.1. **Weak-star convergence.** We first show convergence in the weak-star topology. This allows us to approximate the evolution of the moments of the measure ξ_t using the moments of ξ_t^λ. Given a measure ξ, we denote its support by $\mathrm{supp}(\xi)$, defined as the smallest closed set whose complement has zero measure with respect to ξ. Equivalently, it is the smallest closed set for which every point has a neighborhood of positive measure with respect to ξ.

Proposition 7. *Let $v : \mathbb{R}^n \to \mathbb{R}$ be a continuous function, and assume that ξ_0 has bounded support. Then,*

$$\lim_{\lambda \to 0} \int_{\mathbb{R}^n} v(z)\ d\xi_t^\lambda(z) = \int_{\mathbb{R}^n} v(z)\ d\xi_t(z). \tag{18}$$

Proof. By definition of the pushforward measure ξ_t^λ, it holds

$$\int_{\mathbb{R}^n} v(z)\ d\xi_t^\lambda(z) = \int_{\mathbb{R}^n} v(F_t^\lambda(y))\ d\xi_0(y) \tag{19}$$

for all continuous functions v. From Theorem 2, for each $t \in [0, T]$, we have $\lim_{\lambda \to 0} z_\lambda(t) = z(t)$, which is equivalent to

$$\lim_{\lambda \to 0}\ F_t^\lambda(y) = F_t(y), \quad \forall y \in S(0).$$

Since v is any continuous function, this implies

$$\lim_{\lambda \to 0}\ v(F_t^\lambda(y)) = v(F_t(y)).$$

By assumption, $v \circ F_t^\lambda$ is bounded on the bounded set $\mathrm{supp}(\xi_0)$. This allows us to invoke Lebesgue's dominated convergence theorem to get

$$\lim_{\lambda \to 0} \int_{\mathbb{R}^n} v(F_t^\lambda(y))\ d\xi_0(y) = \int_{\mathbb{R}^n} v(F_t(y)) d\xi_0(y). \tag{20}$$

Hence, (19) and (20) yield

$$\lim_{\lambda \to 0} \int_{\mathbb{R}^n} v(z)\ d\xi_t^\lambda(z) = \int_{\mathbb{R}^n} v(F_t(y)) d\xi_0(y).$$

Using again the change of variables formula, we obtain

$$\lim_{\lambda \to 0} \int_{\mathbb{R}^n} v(z)\ d\xi_t^\lambda(z) = \int_{\mathbb{R}^n} v(z)\ d\xi_t(z)$$

for all continuous functions v on $\mathbb{R}^n$. Therefore, the equality in (18) is proved. □

Remark 8. In the proof of Proposition 7, the boundedness of $\mathrm{supp}(\xi_0)$ was used to invoke dominated convergence theorem. The result of Proposition 7 extends in some cases where $\mathrm{supp}(\xi_0)$ is unbounded. In particular, if it can be shown that there exists a function $g : [0, T] \times \mathbb{R}^n \to \mathbb{R}_{\geqslant 0}$ such that, for each $\lambda > 0$,

$$\left|F_t^\lambda(y)\right| \leqslant g(t, y), \quad t \in [0, T]$$

then the convergence in (18) holds for all continuous functions v which satisfy

$$\int_{\mathbb{R}^n} v(g(t, y)) d\xi_0(y) < \infty, \quad t \in [0, T].$$

4.2. **Relations Describing Moments.** An immediate consequence of Proposition 7 is that we can get a desired approximation of the moments of ξ_t by choosing appropriate test functions v. This amounts to computing the moments of ξ_t^λ. We will now explore numerical techniques which allow us to compute the solution of (16) by computing the desired moments.

Toward this end, we first observe that the Liouville equation (16) can be equivalently written as a linear PDE satisfied by the occupation measures

$$d\mu^\lambda := dt\ d\xi_t^\lambda, \quad with \quad \mu_0^\lambda := \delta_0 \xi_0,\ \mu_T^\lambda := \delta_T \xi_T,$$

which is

$$\partial_t \mu^\lambda + \operatorname{div}(\mu^\lambda f_\lambda) + \mu_T^\lambda = \mu_0^\lambda \tag{21}$$

which again should be understood in the sense of distributions, i.e.

$$\int_{\mathbb{R}_+}\int_{\mathbb{R}^n} (\partial_t v(t,z) + \partial_z v(t,z)\cdot f_\lambda(t,z))\, d\mu^\lambda(t,z) = \int_{\mathbb{R}_+}\int_{\mathbb{R}^n} v(t,z)(d\mu_T^\lambda(t,z) - d\mu_0^\lambda(t,z)),$$

for all continuously differentiable functions v.

We compute approximate moments of μ^λ by applying the moment-SOS hierarchy [27]. This method consists of minimizing a functional subject to the following constraints:

(1) The *Liouville* equation (21) expressed in the sense of distributions, as a linear constraints on the moments of μ^λ and μ_T^λ.
(2) Necessary linear matrix inequality (LMI) constraints based on the dual of Putinar's Positivstellensatz.

We will see in the following how to formulate the *Liouville* equation (21) as a linear moment constraint.

Let g be a polynomial vector field defined as

$$g : \underbrace{(z_1, z_2, \dots, z_n)}_{z} \in \mathbb{R}^n \mapsto (g_1, g_2, \dots, g_n) \in \mathbb{R}^n,$$

and v be a monomial test function, with a maximum degree $d \in \mathbb{N}$, defined as

$$v : (t,z) \mapsto t^a z^b := t^a z_1^{b_1} z_2^{b_2} \cdots z_n^{b_n},$$

for all $(a,b) \in \mathbb{N}^{n+1}$, with $a + b_1 + b_2 + \cdots + b_n \leqslant d$. The maximal degree d is called the relaxation degree.

Besides, let us denote

$$y_{a-1,b} := \int_0^T \int_{\mathbb{R}^n} t^{a-1} z^b d\mu^\lambda(t,z) \tag{22}$$

and

$$y_{a,b}^T := \int_0^T \int_{\mathbb{R}^n} t^a z^b d\mu_T^\lambda(t,z), \tag{23}$$

$$y_{a,b}^0 := \int_0^T \int_{\mathbb{R}^n} t^a z^b\ d\mu_0^\lambda(t,z). \tag{24}$$

Let e_i denote the vector whose only non-zero entry is equal to one at position i.

Proposition 9. *The Liouville equation (21) is equivalently expressed as:*

$$y_{a,b}^T - y_{a,b}^0 = a y_{a-1,b} + \sum_{i=1}^n \int_0^T \int_{\mathbb{R}^n} b_i t^a z^{b-e_i} g_i(z)\ d\mu^\lambda(t,z) \tag{25}$$

which are linear constraints that link the moments of the initial measure, terminal measure and occupation measure.

Proof. Choosing $v(t,z) = t^a z^b$ as a monomial test function, the *Liouville* equation (21) is then written as

$$\langle \partial_t \mu^\lambda, v\rangle + \langle \mathrm{div}(\mu^\lambda g), v\rangle + \langle \mu_T^\lambda, v\rangle = \langle \mu_0^\lambda, v\rangle,$$

which implies

(26)
$$\int_0^T \int_{\mathbb{R}^n} (\partial_t v(t,z) + \partial_z v(t,z)\cdot g(z))\, d\mu^\lambda(t,z) = \int_0^T \int_{\mathbb{R}^n} v(t,z)\, (d\mu_T^\lambda(t,z) - d\mu_0^\lambda(t,z)).$$

We have

$$\partial_t v(t,z) = a t^{a-1} z^b,$$

and

$$\partial_z v(t,z) = (b_1 t^a z_1^{b_1-1} z_2^{b_2} \cdots z_n^{b_n}, b_2 t^a z_1^{b_1} z_2^{b_2-1} \cdots z_n^{b_n}, \ldots, b_n t^a z_1^{b_1} z_2^{b_2} \cdots z_n^{b_n-1}).$$

Replacing $\partial_t v(t,z)$ and $\partial_z v(t,z)$ by their expressions in (26) yields

$$\begin{aligned}&\int_0^T \int_{\mathbb{R}^n} (a t^{a-1} z^b + \sum_{i=1}^n b_i t^a z^{b-e_i} g_i(z))\, d\mu^\lambda(t,z)\\ &= \int_0^T \int_{\mathbb{R}^n} t^a z^b\, d\mu_T^\lambda(t,z) - \int_0^T \int_{\mathbb{R}^n} t^a z^b\, d\mu_0^\lambda(t,z)\end{aligned}$$

which is the expected statement by using the notations (22), (23) and (24). □

4.3. **Numerical computation.** Based on the result of Proposition 9, we now describe a numerical method for computing $y_{a,b}^T$. It is assumed that the initial measure $d\mu_0$ is given, which allows us to compute $y_{a,b}^0$. We next describe the main steps involved in writing a semidefinite program for calculating $y_{a,b}^T$ corresponding to the measure $d\mu^\lambda$. Note that, for each $\lambda > 0$, the measure μ^λ is supported on a subset of $\mathbb{R}^{n+1}$. In what follows, we provide some elements of construction for our algorithm for a finite Borel measure μ supported on $\mathbb{R}^p$.

Given a Borel probability measure μ and $\alpha \in \mathbb{N}^p$, we let

$$y_\alpha(\mu) = \int_{\mathbb{R}^p} z^\alpha d\mu(z),$$

where we recall that $z^\alpha := z^{\alpha_1} z^{\alpha_2} \ldots z_p^{\alpha_p}$. We consider the set $\{\alpha \in \mathbb{N}^p;\ \alpha_1 + \cdots + \alpha_p \leqslant d\}$ with graded lexicographic order, and denote it by $\mathbb{N}_d^p$; for example, with $p = 2$, $d = 2$, $\mathbb{N}_2^2 = \{(0,0),(1,0),(0,1),(2,0),(1,1),(0,2)\}$. The cardinality of $\mathbb{N}_d^p$ is $s(d) := \binom{p+d}{d}$, which is the number of monomials of degree at most d. The sequence $y = (y_\alpha(\mu))_{\alpha\in\mathbb{N}^p}$ therefore encodes the moments of the measure μ.

The moment matrix of degree d associated with a Borel measure μ, denoted by $M_d(\mu)$ is a matrix of dimension $s(d)\times s(d)$, whose rows and columns are indexed by monomials of degree at most d. For $\alpha, \beta \in \mathbb{N}_d^p$, the corresponding entry in $M_d(\mu)$ is defined by $(M_d(\mu))_{\alpha,\beta} := y_{\alpha+\beta}(\mu)$. As an example, once again with $p = 2$, $d = 2$, $M_2(\mu) \in \mathbb{R}^{6\times 6}$, and the element in second row ($\alpha = (1,0)$), third column ($\beta = (0,1)$), corresponds to $\int_{\mathbb{R}^2} z_1 z_2\, d\mu(z)$.

To see an alternate representation of $M_d(\mu)$, let $b_d(z) := (z^\alpha)_{\alpha\in\mathbb{N}_d^p} \in \mathbb{R}[z]_d^{s(d)}$ denote the vector of monomials of degree less than or equal to d, with graded lexicographic order. If the sequence $\{y_\alpha\}_{\alpha\in\mathbb{N}^p}$ has a representing measure μ, i.e. $y_\alpha = \int_{\mathbb{R}^p} z^\alpha d\mu(z)$ for all $\alpha \in \mathbb{N}^p$, we can use the equivalent definition $M_d(\mu) :=$

$\int_{\mathbb{R}^p} b_d(z)b_d(z)^\top \, d\mu(z)$, where the integral is understood entrywise. We can also define the localizing matrix of degree d with respect to a given $q(z) \in \mathbb{R}[z]$ by

$$M_{d-\lceil \deg(q)/2 \rceil}(q\mu) := \int_{\mathbb{R}^p} q(z)b_d(z)b_d(z)^\top \, d\mu(z)$$

where $\lceil x \rceil$ denotes the smallest integer greater than x.

Assume that $X \subset \mathbb{R}^n$ is a compact basic semialgebraic set i.e.

$$X := \{z \in \mathbb{R}^n : p_k(z) \geqslant 0, \;\; k = 0, \dots, n_X\}$$

for given $p_k \in \mathbb{R}[z]$, $k = 0, \dots, n_X$. Let $p_0(z) = 1$ and let one of the inequalities $p_k(z) \geqslant 0$ be of the form $R - \sum_{i=1}^n z_i^2 \geqslant 0$ where R is a sufficiently large positive constant.

Proposition 10. *(Putinar's Theorem) The sequence of moments y has a representing measure supported on X if and only if $M_{d-\lceil \deg p_k/2 \rceil}(p_k\mu)$, $k = 0, \dots, n_X$ are positive semidefinite for all $d \in \mathbb{N}$.*

The moment-SOS hierarchy, based on Proposition 10, allows us to compute approximate moments of the occupation measure and terminal measures. Recall that the moments of the initial measure are given since the initial measure is given. We fix a degree $d \in \mathbb{N}$ and we consider the linear constraint (25) linking moments of degree up to d, and subject to the constraints that the localizing matrices of the occupation measure and terminal measure, truncated to moments of degree up to d, are all positive semi-definite. This results in a finite-dimensional feasibility problem describe by linear matrix inequalities. The higher is the relaxation degree d, the better are the approximate moments, in the sense that when d tends to infinity, Proposition 10 and linear constraint (25) ensure that we have indeed moments of measures satisfying the Liouville equation.

The LMI constraints are automatically constructed by the `msdp` command in Gloptipoly for Matlab [28]. For more details about the LMI constraints, we refer the reader to [25, Section 3.3] or the two introductory chapters of [27].

5. Convergence of Support of Measures

For several applications, it is important to approximate the support of the measure ξ_t, since it provides a probabilistic estimate of the state trajectories at time $t \in [0, T]$. Once again, our goal is to approximate the support of ξ_t by the support of ξ_t^λ where ξ_t^λ satisfies (16).

5.1. Hausdorff convergence of support.

We first show that $\mathrm{supp}(\xi_t^\lambda)$ converges in the Hausdorff distance to $\mathrm{supp}(\xi_t)$.

Proposition 11. *For each $t \in [0, T]$, it holds*

$$\lim_{\lambda \to 0} d_H(\mathrm{supp}(\xi_t^\lambda), \mathrm{supp}(\xi_t)) = 0. \tag{27}$$

Proof. First, let $A_t^\lambda := \mathrm{supp}(\xi_t^\lambda)$ and $A_t := \mathrm{supp}(\xi_t)$. For proving that $\lim_{\lambda \to 0} d_H(A_t^\lambda, A_t) = 0$, we need to prove the following two limits:

$$\lim_{\lambda \to 0} \sup_{y_\lambda \in A_t^\lambda} d(y_\lambda, A_t) = 0, \tag{28}$$

and

$$\lim_{\lambda \to 0} \sup_{x \in A_t} d(x, A_t^\lambda) = 0. \tag{29}$$

For proving (28), we first observe that

$$\sup_{y_\lambda \in A_t^\lambda} d(y_\lambda, A_t) = \sup_{y_\lambda \in A_t^\lambda} \inf_{x \in A_t} |y_\lambda - x|,$$

and hence it needs to be shown that for every $y_\lambda \in A_t^\lambda$, there exists $x \in A_t$ such that $|x - y_\lambda|$ converges to zero as λ converges to zero. Since $y_\lambda \in A_t^\lambda$, there exists $z_0 \in \mathrm{supp}(\xi_0)$ such that $y_\lambda = F_t^\lambda(z_0)$. By choosing $x = F_t(z_0) \in A_t$, it follows from Theorem 2 that $\lim_{\lambda\to 0} F_t^\lambda(z_0) = F_t(z_0)$, or equivalently, $|x - y_\lambda|$ converges to 0 as $\lambda \to 0$.

For proving (29), we similarly observe that

$$\sup_{x\in A_t} d(x, A_t^\lambda) = \sup_{x\in A_t} \inf_{y_\lambda \in A_t^\lambda} |x - y_\lambda|.$$

Following the same idea as before, let us take $x \in A_t$, then there exists $z_0 \in \mathrm{supp}(\xi_0)$ such that $x = F_t(z_0)$. By choosing $y_\lambda = F_t^\lambda(z_0) \in A_t^\lambda$, it again follows from Theorem 2 that $|x - y_\lambda|$ converges to 0 as $\lambda \to 0$, and (29) is obtained. □

5.2. **Approximation of support.** Just like the approximation of moments, we can provide some numerical methods to approximate the support of the sequence of measures ξ_t^λ. By Proposition 11, by computing such an approximation for $\lambda > 0$ sufficiently small, we get an approximation of the support of the probability measure ξ_t for the original system.

The technique we present is based on approximating the support of a measure by the sublevel sets of a polynomial function. In particular, for a finite Borel measure μ, we consider the moment matrix $M_d(\mu)$ and introduce the mapping,

$$\mathbb{R}^n \ni x \mapsto \Lambda_{\xi,d}(x) := b_d(x)^\top M_d(\mu)^{-1} b_d(x) \in \mathbb{R},$$

which we call Christoffel-Darboux polynomial. Thus, the basic idea behind the construction of the support of the measure μ is to use the finite order moments, and show that the sublevel sets of the Christoffel-Darboux polynomial indeed converge to the actual support of μ. This technique has been proposed in [30] for stationary measures under certain hypothesis. Here, we show that by placing certain hypothesis on the initial measure ξ_0, the approximations ξ_t^λ obtained by the Liouville equation satisfy the required hypothesis, which allow us to approximate the support of ξ_t^λ by constructing the corresponding Christoffel-Darboux polynomial.

The following statement shows the existence of a sublevel set that approximates the support of the sequence of measures ξ_t^λ, when λ and $t \in [0, T]$ are fixed.

Proposition 12. *Let ξ_0 be absolutely continuous with respect to the Lebesgue measure and let us suppose that $\mathrm{supp}(\xi_0)$ is compact. For a fixed $\lambda > 0$, and $t \in [0, T]$, consider ξ_t^λ obtained by solving (16), and $M_{d,t}^\lambda(\xi_t^\lambda)$ the corresponding moment matrix of degree d. For every $\epsilon > 0$ (small enough), there exists $d \in \mathbb{N}$ (large enough) and $\gamma_d > 0$, such that the sublevel set*

$$S_{d,t}^\lambda := \{z \in \mathbb{R}^p \mid b_d(z)^\top M_{d,t}^\lambda(\xi_t^\lambda)^{-1} b_d(z) \leqslant \gamma_d\} \tag{30}$$

satisfies

$$d_H(S_{d,t}^\lambda, \mathrm{supp}(\xi_t^\lambda)) \leqslant \epsilon, \tag{31}$$

as $d \to +\infty$.

Proof. For each $\lambda > 0$ and $t \in [0, T]$, if we show that

- The set $\mathrm{supp}(\xi_t^\lambda)$ is compact and has nonempty interior.
- It holds that ξ_t^λ is absolutely continuous with respect to the Lebesgue measure.

then, the statement follows by applying [30, Theorem 3.11] to the measure ξ_t^λ.

The aforementioned properties basically follow from the fact that, for a fixed $t \in [0, T]$ and $\lambda > 0$, the mapping $F_t^\lambda : \mathbb{R}^n \to \mathbb{R}^n$ is a homeomorphism obtained from the solution of an ODE with Lipschitz continuous right-hand side (9). Let L^λ denote the (uniform with respect to time) Lipschitz constant for the mapping on

the right-hand side of (9). One can readily show that for a pair of initial conditions y_0, z_0 and $y_t := F_t^\lambda(y_0)$, $z_t := F_t^\lambda(z_0)$, it holds that

$$|z_0 - y_0| \exp(-L^\lambda t) \leqslant |z_t - y_t| \leqslant |z_0 - y_0| \exp(L^\lambda t).$$

Using this estimate, and recalling that $\xi_0^\lambda = \xi_0$, it readily follows that $\mathrm{supp}(\xi_t^\lambda)$ is compact and has nonempty interior under the given hypothesis on ξ_0.

Absolute continuity of ξ_t^λ with respect to Lebesgue measure holds if ξ_t^λ is absolutely continuous with respect to ξ_0. The later indeed holds because for every measurable set A, Lipschitz continuity of F_t^λ implies that

$$\xi_0(A) = 0 \Rightarrow \xi_t^\lambda(A) = \xi_0((F_t^\lambda)^{-1}(A)) = 0, \tag{32}$$

whence the desired result follows. □

6. Illustrative example

In this section, we give an example that illustrates the computation of the moments associated with ξ_t^λ of the regularized system (9) in the case where $f : \mathbb{R}^2 \to \mathbb{R}^2$, by applying the moment-SOS hierarchy [27].

Consider the constrained system (7) of Example 1 where $f(z) = Az$ with $A = \left[\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right]$ and $S = \mathbb{R}^2_+$. Let us write the regularized system (9) in polar coordinates (r, θ) as follows:

$$\begin{cases} \dot{r}(t) = 0, \\ \dot{\theta}_\lambda(t) = -1 - \frac{1}{\lambda}(\theta_\lambda(t) - \mathrm{proj}(\theta_\lambda(t), S(t))). \end{cases}$$

or equivalently:

$$\begin{cases} \dot{r}(t) = 0, \\ \dot{\theta}_\lambda(t) = -1 - \frac{1}{\lambda}(\theta_\lambda(t) - \max(\theta_\lambda(t), 0)). \end{cases} \tag{33}$$

Let $d = 4$ be the degree of relaxation, and let us choose different values of the regularization parameter $\lambda \in \{0.05, 0.1, 0.5\}$. We introduce the initial measure as a Dirac measure with respect to time product a uniform measure in $[0, 1] \times [0, \frac{1}{2}]$ with respect to the state.

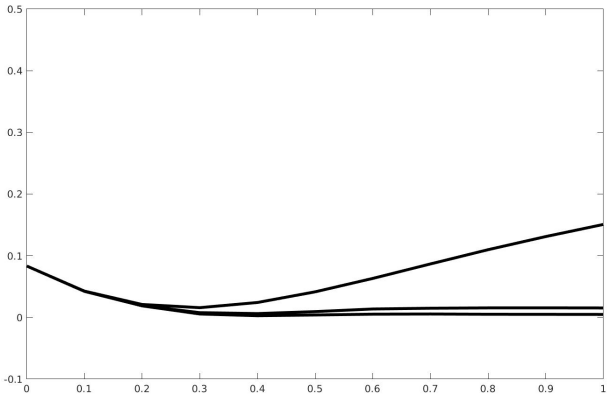

Figure 3. First order moment of the second state (vertical axis) of the occupation measure of the regularized system, as a function of time (horizontal axis), for different values of the regularization parameter (top curve $\lambda = 0.5$, middle curve $\lambda = 0.1$, bottom curve $\lambda = 0.05$)

We calculate the moment of the initial measure to replace it directly in Liouville constraint (25), where the variables z_1 and z_2 in (25) are respectively r and θ. For all $(a, b_1, b_2) \in \mathbb{N}^3$, with $a + b_1 + b_2 \leqslant d$, the moment of the initial measure is then given as

$$\begin{aligned}\int_0^T \int_{\mathbb{R}^n} t^a z_1^{b_1} z_2^{b_2} \; d\mu_0(t,z) &= \int_0^T \int_{\mathbb{R}^n} t^a z_1^{b_1} z_2^{b_2} \; \delta_0(dt)\lambda_{[0,1]}(dz_1)\lambda_{[0,\frac{1}{2}]}(dz_2) \\ &= 0^a \int_0^1 z_1^{b_1} \; dz_1 \int_0^{\frac{1}{2}} 2 z_2^{b_2} \; dz_2 \\ &= 0^a \frac{1}{b_1+1}\left(1^{b_1+1} - 0^{b_1+1}\right) \frac{2}{b_2+1}\left(\left(\frac{1}{2}\right)^{b_2+1} - 0^{b_2+1}\right).\end{aligned}$$

Then we apply the moment-SOS hierarchy [27] which allows us to approximate numerically the moments of the unknown occupation measure and terminal measure. For different values of the terminal time $T \in \{0, 0.1, 0.2, \ldots, 1\}$, this gives us:

- The evolution of the moment $\int r(t)^2 \; d\mu_T^\lambda$ as a function of time, which we observe numerically is a constant for different values of the regularization parameter λ.
- The evolution of the moment $\int \theta(t)^2 \; d\mu_T^\lambda$ as a function of time for different values of the regularization parameter λ, which is illustrated on Figure 3.

7. Conclusions

In this article, we studied the time evolution of nonsmooth constrained dynamical systems when the initial condition is described by a probability measure. Unlike conventional ODEs, it is not obvious how to describe the time evolution of the image measure by the flow as a Liouville PDE. To circumvent this issue, we propose an approximation technique based on constructing Lipschitz approximations for the original nonsmooth system, and then using the Liouville equation for the approximate Lipschitz dynamics. Numerical methods for computing the approximation of solutions of Liouville equation then allow us to compute the moments and support of the probability measures associated to the original system. While evolution of probability measure for a class of constrained systems has been studied in [21], here we adopted a different approach for computing the approximations of differential equations associated with the evolution of probability measure. To seek generality in the class of systems studied in our work, one could, just like [21], consider a congestion constraint formulated as a uniform bound on the density of the measure. With the method proposed in this article, we can readily deal with such constraints, which would translate into a linear semidefinite constraint on the moments.

To seek improvements in the approach adopted in this paper, it is observed that the proposed Lipschitz approximations are difficult to simulate numerically. In particular, for the illustrated example, we implemented the projection map onto a cone by splitting the Liouville equation in different parts, where each of them corresponds to the region where the approximating ODE is continuous. One could use some recent work on approximating ODEs with twice differentiable right-hand side [20] to see if the resulting implementation is easier to simulate for a broader class of constraint sets.

Another potential direction of research that comes out from this work is the possibility of using the proposed tools for optimal control problems. As was done for ODEs [31], it is possible to use the formalism of Liouville equation for optimal control problems. The optimal control for the class of nonsmooth systems studied in this paper is a challenging problem, and it has been addressed recently in [14, 19, 39].

It would be interesting to see if the methods proposed in this paper provide a numerically constructive solution to such challenging problems.

Appendix A. Proofs of Lemmas in Theorem 2

A.1. **Proof of Lemma 3.** For each $\lambda > 0$, the dynamics for z_λ in (9) yield

$$\begin{aligned} |\dot{z}_\lambda(t)| &= |f(t, z_\lambda(t)) - \frac{1}{\lambda}(z_\lambda(t) - \mathrm{proj}(z_\lambda(t), S(t)))| \\ &\leqslant |f(t, z_\lambda(t))| + \frac{1}{\lambda}|z_\lambda(t) - \mathrm{proj}(z_\lambda(t), S(t))|. \end{aligned} \tag{34}$$

For the first term in the right-hand side of (34), we have that

$$|f(t, z_\lambda(t))| \leqslant L_f(1 + |z_\lambda(t)|). \tag{35}$$

For the second term in the right-hand side of (34), we introduce the function $d_\lambda(t) = \inf_{y \in S(t)} |y - z_\lambda(t)|$, so that $d_\lambda(t) = d_{S(t)}(z_\lambda(t))$. It is seen that $d_\lambda(t) = |z_\lambda(t) - \mathrm{proj}(z_\lambda(t), S(t))|$. So $\frac{1}{\lambda}|z_\lambda(t) - \mathrm{proj}(z_\lambda(t), S(t))| = \frac{1}{\lambda} d_\lambda(t)$.
To obtain a bound on $d_\lambda(t)$, we compute the derivative of $d^2_\lambda(t)$:

$$\begin{aligned} \frac{d}{dt} d^2_\lambda(t) &= \frac{d}{dt} d^2_{S(t)}(z_\lambda(t)) \\ &= \lim_{\epsilon \to 0} \frac{d^2_{S(t+\epsilon)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t))}{\epsilon} \\ &= \lim_{\epsilon \to 0} \frac{d^2_{S(t+\epsilon)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t+\epsilon))}{\epsilon} + \frac{d^2_{S(t)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t))}{\epsilon}. \end{aligned} \tag{36}$$

For the first term in the limit, we use that

$$\begin{aligned} & d^2_{S(t+\epsilon)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t+\epsilon)) \\ &\leqslant d_H(S(t+\epsilon), S(t)) \big(d_{S(t+\epsilon)}(z_\lambda(t+\epsilon)) + d_{S(t)}(z_\lambda(t+\epsilon)) \big) \\ &\leqslant |\epsilon| L_S \big(d_{S(t+\epsilon)}(z_\lambda(t+\epsilon)) + d_{S(t)}(z_\lambda(t+\epsilon)) \big). \end{aligned} \tag{37}$$

For the second term in the limit, we first notice that

$$\begin{aligned} d^2_{S(t)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t)) &= d^2_{S(t)}(z_\lambda(t) + \epsilon \dot{z}_\lambda(t)) - d^2_{S(t)}(z_\lambda(t)) \\ &\quad + \big(d_{S(t)}(z_\lambda(t+\epsilon)) - d_{S(t)}(z_\lambda(t) + \epsilon \dot{z}_\lambda(t)) \big) \\ &\quad \big(d_{S(t)}(z_\lambda(t+\epsilon)) + d_{S(t)}(z_\lambda(t) + \epsilon \dot{z}_\lambda(t)) \big). \end{aligned}$$

Since $z_\lambda(.)$ is differentiable, $z_\lambda(t+\epsilon) = z_\lambda(t) + \epsilon \dot{z}_\lambda(t) + \mathcal{O}(\epsilon)$ and hence $d_{S(t)}(z_\lambda(t+\epsilon)) - d_{S(t)}(z_\lambda(t) + \epsilon \dot{z}_\lambda(t)) = \mathcal{O}(\epsilon)$. This implies that

$$d^2_{S(t)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t)) = d^2_{S(t)}(z_\lambda(t) + \epsilon \dot{z}_\lambda(t)) - d^2_{S(t)}(z_\lambda(t)).$$

And,

$$\begin{aligned} \lim_{\epsilon \to 0} \frac{1}{\epsilon} \left[d^2_{S(t)}(z_\lambda(t+\epsilon)) - d^2_{S(t)}(z_\lambda(t)) \right] &= \langle \nabla d^2_{S(t)}(z_\lambda(t)), \dot{z}_\lambda(t) \rangle \\ &= 2 \langle z_\lambda(t) - \mathrm{proj}(z_\lambda(t), S(t)), \dot{z}_\lambda(t) \rangle. \end{aligned} \tag{38}$$

By substitution of (37) and (38) in equation (36), we obtain

$$\begin{aligned} \frac{d}{dt} d^2_\lambda(t) = 2 d_\lambda(t) \dot{d}_\lambda(t) &\leqslant 2 d_\lambda(t) \dot{z}_\lambda(t) + 2 L_S d_\lambda(t) \\ &\leqslant 2 d_\lambda(t) \left(f(t, z_\lambda(t)) - \frac{1}{\lambda} d_\lambda(t) \right) + 2 L_S d_\lambda(t) \\ &\leqslant -\frac{2}{\lambda} d^2_\lambda(t) + 2 d_\lambda(t) f(t, z_\lambda(t)) + 2 L_S d_\lambda(t). \end{aligned}$$

Dividing by $2d_\lambda(t)$, we get

$$\frac{d}{dt}d_\lambda(t) \leqslant -\frac{1}{\lambda}d_\lambda(t) + f(t, z_\lambda(t)) + L_S,$$

which implies that,

$$d_\lambda(t) \leqslant e^{-t/\lambda}d_\lambda(0) + \int_0^t e^{-(t-s)/\lambda}(f(s, z_\lambda(s)) + L_S)\ ds.$$

Or, $d_\lambda(0) = |z_0 - \text{proj}(z_0, S(0))| = 0$ since $z_0 \in S(0)$ and we have that f satisfies (35), then it follows

$$\frac{1}{\lambda}d_\lambda(t) \leqslant \frac{1}{\lambda}\int_0^t e^{-(t-s)/\lambda}(L_f + L_f|z_\lambda(s)| + L_S)\ ds. \tag{39}$$

And therefore, substituting (35) and (39) in (34), we get

$$\begin{aligned}
|\dot{z}_\lambda(t)| &\leqslant L_f + L_f|z_\lambda(t)| + \frac{1}{\lambda}\int_0^t e^{-(t-s)/\lambda}(L_f + L_f|z_\lambda(s)| + L_S)\ ds \\
&\leqslant L_f + L_f|z_\lambda(t)| + \frac{L_f}{\lambda}\int_0^t e^{-(t-s)/\lambda}\ ds + \frac{L_f}{\lambda}\int_0^t e^{-(t-s)/\lambda}|z_\lambda(s)|\ ds \\
&\quad + \frac{L_S}{\lambda}\int_0^t e^{-(t-s)/\lambda}\ ds.
\end{aligned}$$

We have

$$\begin{aligned}
\frac{L_f}{\lambda}\int_0^t e^{-(t-s)/\lambda}\ ds &= \frac{L_f}{\lambda}e^{-t/\lambda}\left[\lambda e^{s/\lambda}\right]_0^t = \frac{L_f}{\lambda}e^{-t/\lambda}\left(\lambda e^{t/\lambda} - \lambda\right) \\
&= L_f\left(1 - e^{-t/\lambda}\right) \leqslant L_f.
\end{aligned}$$

Similarly,

$$\frac{L_S}{\lambda}\int_0^t e^{-(t-s)/\lambda}\ ds \leqslant L_S.$$

Besides, we have

$$\begin{aligned}
\frac{L_f}{\lambda}\int_0^t e^{-(t-s)/\lambda}|z_\lambda(s)|\ ds &\leqslant \underbrace{\frac{L_f}{\lambda}\int_0^t e^{-(t-s)/\lambda}\ ds}_{\leqslant L_f} \cdot \max_{0\leqslant s\leqslant t}|z_\lambda(s)| \\
&\leqslant L_f \max_{0\leqslant s\leqslant t}|z_\lambda(s)|.
\end{aligned}$$

The bound of $|\dot{z}_\lambda(t)|$ is then expressed as

$$|\dot{z}_\lambda(t)| \leqslant 2L_f + L_f|z_\lambda(t)| + L_f \max_{0\leqslant s\leqslant t}|z_\lambda(s)| + L_S.$$

A.2. **Proof of Lemma 5.** Let $\bar{z}_\lambda(s) := \text{proj}(z_\lambda(s), S(s))$; then $s \mapsto \bar{z}_\lambda(s)$ is a continuous mapping. Since $\varphi(s) + \int_{t_1}^s f(r, z_\lambda(r))\ dr \in S(s)$ and λ is positive, it follows from the definition of the projections that

$$\begin{aligned}
&\left\langle \varphi(s) + \int_{t_1}^s f(r, z_\lambda(r))\ dr - \bar{z}_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s))\right\rangle \\
&= \frac{1}{\lambda}\left\langle \varphi(s) + \int_{t_1}^s f(r, z_\lambda(r))\ dr - \bar{z}_\lambda(s), \bar{z}_\lambda(s) - z_\lambda(s)\right\rangle \geqslant 0.
\end{aligned}$$

Then

$$\left\langle \varphi(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s))\right\rangle \geqslant \left\langle \bar{z}_\lambda(s) - \int_{t_1}^s f(r, z_\lambda(r))\ dr, \dot{z}_\lambda(s) - f(s, z_\lambda(s))\right\rangle,$$

which implies that,

$$\int_{t_1}^{t_2} \big\langle \varphi(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \, ds \geqslant \int_{t_1}^{t_2} \big\langle \bar{z}_\lambda(s) - \int_{t_1}^{s} f(r, z_\lambda(r)) \, dr, \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \, ds.$$

Since at the points where $z_\lambda(.)$ is differentiable, we have

$$\begin{aligned} \langle \bar{z}_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \rangle &= \langle \bar{z}_\lambda(s) - z_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \rangle \\ &\quad + \langle z_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \rangle \\ &= \underbrace{\frac{1}{\lambda} |\bar{z}_\lambda(s) - z_\lambda(s)|^2}_{\geqslant 0} + \langle z_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \rangle, \end{aligned}$$

it follows that,

$$\langle \bar{z}_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \rangle \geqslant \langle z_\lambda(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \rangle,$$

and,

$$\int_{t_1}^{t_2} \big\langle \varphi(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \, ds \geqslant \int_{t_1}^{t_2} \big\langle z_\lambda(s) - \int_{t_1}^{s} f(r, z_\lambda(r)) \, dr, \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \, ds.$$

We have

$$\begin{aligned} &\int_{t_1}^{t_2} \big\langle z_\lambda(s) - \int_{t_1}^{s} f(r, z_\lambda(r)) \, dr, \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \, ds \\ &= \frac{1}{2} \left[\| z_\lambda(s) - \int_{t_1}^{s} f(r, z_\lambda(r)) \, dr \|^2 \right]_{t_1}^{t_2} \\ &= \frac{1}{2} \left(\| z_\lambda(t_2) - \int_{t_1}^{t_2} f(r, z_\lambda(r)) \, dr \|^2 - \| z_\lambda(t_1) \|^2 \right), \end{aligned}$$

hence, we obtain that

$$\int_{t_1}^{t_2} \big\langle \varphi(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \, ds \geqslant \frac{1}{2} \left(\| z_\lambda(t_2) - \int_{t_1}^{t_2} f(r, z_\lambda(r)) \, dr \|^2 - \| z_\lambda(t_1) \|^2 \right).$$

We take limits with respect to $\lambda \to 0$. Since $z_\lambda(.)$ converges pointwise to $z(.)$, we have $\big\langle \varphi(s), \dot{z}_\lambda(s) - f(s, z_\lambda(s)) \big\rangle \longrightarrow \big\langle \varphi(s), \dot{z}(s) - f(s, z(s)) \big\rangle$ for each $s \in [t_1, t_2]$, and $\| z_\lambda(t_2) - \int_{t_1}^{t_2} f(r, z_\lambda(r)) \, dr \|^2 \longrightarrow \| z(t_2) - \int_{t_1}^{t_2} f(r, z(r)) \, dr \|^2$, and $\| z_\lambda(t_1) \|^2 \longrightarrow \| z(t_1) \|^2$.

Therefore, this yields to

$$\int_{t_1}^{t_2} \big\langle \varphi(s), \dot{z}(s) - f(s, z(s)) \big\rangle \, ds \geqslant \frac{1}{2} \left(\| z(t_2) - \int_{t_1}^{t_2} f(r, z(r)) \, dr \|^2 - \| z(t_1) \|^2 \right),$$

and Lemma 5 is then proved.
