THE MOMENT-SOS HIERARCHY: APPLICATIONS AND RELATED TOPICS

JEAN B. LASSERRE

ABSTRACT. The Moment-SOS hierarchy initially introduced in optimization in 2000, is based on the theory of the $S$-moment problem and its dual counterpart, polynomials that are positive on $S$. It turns out that this methodology can be also applied to solve problems with positivity constraints “$f(x) \geq 0$ for all $x \in S$” and/or linear constraints on Borel measures. Such problems can be viewed as specific instances of the “Generalized Moment Problem” (GMP) whose list of important applications in various domains of science and engineering is almost endless. We describe this methodology in optimization and in two other applications as well for illustration purposes. Finally we also introduce the Christoffel function and reveal its links with the Moment-SOS hierarchy and positive polynomials.

1. Introduction

The Moment-SOS hierarchy was initially designed to help solve polynomial optimization problems (POP), that is, optimization problems in the form:

\begin{equation}
\mathbf{P} : \quad f^* = \inf_x \{ f(x) : x \in S \},
\end{equation}

where $f$ is a polynomial and $S \subset \mathbb{R}^d$ is a basic semi-algebraic set, that is,

\begin{equation}
S := \{ x \in \mathbb{R}^d : g_j(x) \geq 0, \quad j = 1, \ldots, m \},
\end{equation}

for some polynomials $g_j, j = 1, \ldots, m$. Importantly, the description of $\mathbf{P}$ is entirely algebraic via its polynomial data $f, g_j, j = 1, \ldots, m$, which is a crucial feature. (However semi-algebraic functions can also be tolerated to a certain extent.)

As $\mathbf{P}$ is a particular case of Non Linear Programming (NLP), what is so specific about $\mathbf{P}$ in (1)? The answer depends on the meaning of $f^*$ in (1). If one is interested in a local minimum only then the whole arsenal of efficient methods of NLP can be used for solving $\mathbf{P}$ and its algebraic features are not really exploited.

On the other hand, if $f^*$ in (1) is understood as the global minimum of $\mathbf{P}$ then the situation is totally different. Why? First, to eliminate any ambiguity on the meaning of $f^*$, rewrite (1) as:

\begin{equation}
\mathbf{P} : \quad f^* = \sup \{ \lambda : f(x) - \lambda \geq 0, \forall x \in S \},
\end{equation}

This work is supported by the ANR-NuSCAP 20-CE-48-0014 program and also the AI Interdisciplinary Institute ANITI funding through the French program “Investing for the Future P13A” under the grant agreement number ANR-19-P13A-0004. This research is also part of the programme DesCartes and is supported by the National Research Foundation, Prime Minister’s Office, Singapore under its Campus for Research Excellence and Technological Enterprise (CREATE) programme.
because then indeed $f^*$ is necessarily the global minimum of $P$. In full generality $P$ is very difficult to solve as it is NP-hard. The reason is:

*Given $\lambda \in \mathbb{R}$, checking whether “$f(x) - \lambda \geq 0$ for all $x \in S$” is difficult.*

Indeed, by its very nature this positivity constraint is global and therefore cannot be handled by standard NLP optimization algorithms which use only local information around a current iterate $x \in S$. Therefore to compute $f^*$ in (3) one needs to handle the positivity constraint “$f(x) - \lambda \geq 0$ for all $x \in S$” in some efficient manner. Fortunately, if the data are algebraic then:

1. Powerful positivity certificates from Real Algebraic Geometry (*Positivstellensätze* in German) are available.
2. Some of these positivity certificates have an efficient practical implementation via Linear Programming (LP) or Semidefinite Programming (SDP). In particular and crucially, testing whether a given polynomial is a sum of squares (SOS) simply reduces to solving a single SDP (which can be done in time polynomial in the input size of the polynomial, up to arbitrary fixed precision).

After the pioneers works of [123] and [92], [54, 55] and [106, 107] have been the first to provide a systematic use of these two key ingredients in Optimization and Control, with convergence guarantees. It is also worth mentioning another closely related pioneer work, namely the celebrated SDP-relaxation of [32] which provides a 0.878 approximation guarantee for MAXCUT, a famous problem in non-convex combinatorial optimization (and probably the simplest one). In fact it is perhaps the first famous example of such a successful application of the powerful SDP convex optimization technique to provide guaranteed good approximations to a notoriously difficult non-convex optimization problem. It turns out that this SDP relaxation is precisely the first semidefinite relaxation in the Moment-SOS hierarchy (a.k.a. Lasserre hierarchy) when applied to the MAXCUT problem. This spectacular success story of SDP relaxations has been at the origin of a flourishing research activity in combinatorial optimization and computational complexity. In particular, the study of LP- and SDP-relaxations techniques in hardness of approximation is at the core of a central topic in combinatorial optimization and computational complexity, namely proving/disproving Khot’s famous Unique Games Conjecture\(^2\) (UGC) in Theoretical Computer Science (TCS).

Another (and equivalent) “definition” of the global optimum $f^*$ of $P$ reads:

\[ f^* = \inf_{\phi \in \mathcal{M}(S)_+} \left\{ \int_S f \, d\phi : \quad \phi(S) = 1 \right\}, \]

where the “inf” is over the set $\mathcal{M}(S)_+$ of (positive) Borel measures $\phi$ on $S$. Indeed as $f \geq f^*$ on $S$ and $\phi$ is a probability measure on $S$,

\[ \int_S f \, d\phi \geq \int_S f^* \, d\phi = f^*, \]

\(^1\)In fact see [102] for an update and more details

\(^2\)For this conjecture and its theoretical and practical implications, S. Khot was awarded the prestigious Nevanlinna prize at the ICM 2014 in Seoul [41, 42].
so the infimum in (4) is not smaller than $f^*$. On the other hand, for an arbitrary $x \in S$, its value $f(x)$ is also obtained via $\int_S f \ d\phi$ with $\phi$ being the Dirac probability measure $\delta_x$ at $x \in S$, and so the infimum in (4) is not larger than $f^*$. In particular, if $x^* \in S$ is a global minimizer of $P$ then the Dirac measure $\phi^* := \delta_{x^*}$ at $x^*$ is an optimal solution of (4).

In fact (3) is the LP dual of (4), with $\lambda$ being the dual variable associated with the constraint $\phi(S) = 1$ in (4). In other words, standard LP duality between the two conic programs (4) and (3) nicely captures a convex duality between the "$S$-moment problem" in real and functional analysis, and "polynomials positive on $S$" in real algebraic geometry (more details later).

Moreover, Problem (4) is a very particular instance (and even the simplest instance) of the more general Generalized Moment Problem (GMP) defined by:

$$\inf_{\phi_j \in \mathcal{M}(S_j)} \left\{ \sum_{j=1}^p \int_{S_j} f_j \ d\phi_j : \sum_{j=1}^p f_{ij} d\phi_j \geq b_i, i = 1, \ldots, s \right\},$$

for some given functions $f_j, f_{ij} : \mathbb{R}^{d_j} \to \mathbb{R}, \ i = 1, \ldots, s$, and sets $S_j \subset \mathbb{R}^{d_j}, \ j = 1, \ldots, p$. The GMP (5) is an infinite-dimensional LP with dual:

$$\sup_{\lambda_1, \ldots, \lambda_s \geq 0} \left\{ \sum_{i=1}^s \lambda_i b_i : f_j - \sum_{i=1}^s \lambda_i f_{ij} \geq 0 \text{ on } S_j, \ j = 1, \ldots, p \right\}.$$

Therefore it should be of no surprise that the Moment-SOS hierarchy, initially developed for global optimization, also applies to solving the GMP. This is particularly interesting as moments and positive polynomials are at the crossroad of several areas of mathematics [52] and the list of important applications of the GMP is almost endless; see e.g. [52, 60], references therein, and see also Section 6 where for illustration purpose we describe two particular applications.

Finally, since its birth in early 2000 and in view of its so many potential applications, the Moment SOS-hierarchy has gained attention from various research communities with many different contributions ranging from:

(i): its basic application in many (and diverse) areas after modeling the problem as an instance of the GMP. For illustration purpose two examples are described in Section 6; see also [37, 47] and references therein.

(ii): its adaptation and extension to other domains, e.g. Operations Research [104], and entanglement, violation of Bell inequalities in quantum information where its non-commutative version (the Pironio-Navascues-Acin (NPA) hierarchy described in [91]) is also attracting a lot of attention; see also [16] and [105] and references therein.

(iii): its detailed analysis by the TCS research community for hardness of approximation in combinatorial optimization (e.g. in relation with issues around the Unique Game Conjecture). See e.g. [11], [114] and [9].

(iv): analysis of its rate of convergence with very interesting recent results on specific sets; see e.g. [126, 125, 6] and references therein.

(v): development of algorithmic improvements to improve scalability of the standard Moment-SOS hierarchy. One direction is to take into account several
types of sparsity and/or symmetries often present in large scale optimization problems as explained in Section 3.8. Another is to promote alternatives (e.g. first-order methods, second-order cone programming) to the costly interior point algorithm for semidefinite programming; see e.g. [1, 144, 79].

Structure of the paper. For ease of exposition and clarity, the proof of most results in the form of theorems and lemmas is not provided. However, at the end of each section one has included a Notes & Sources subsection with pointers to articles for detailed proofs, and sometimes a discussion and comments on the results.

After introducing some notation and definitions, in Section 3 one describes the Moment-SOS hierarchy of lower bounds which converges to the global minimum in polynomial optimization. In Section 4 one provides a brief description of an alternative, the Moment-LP hierarchy. Section 5 describes the (less known) Moment-SOS hierarchy of upper bounds which also converges to the global minimum. Section 6 is devoted to other applications of the Moment-SOS hierarchy. For illustration purpose one describes how to apply the Moment-SOS hierarchy in two such applications and provides a (non exhaustive) list of references to other ones in various fields. Finally, Section 7 is devoted to the Christoffel function (a classical tool from the theory of orthogonal polynomials and approximation) to reveal its links and connections with optimization and the Moment-SOS hierarchy.

2. Notation, definitions and some preliminaries

2.1. Notation, definitions. Let $\mathbb{R}[x]$ denote the ring of polynomials in the variables $x = (x_1, \ldots, x_d)$ and let $\mathbb{R}[x]_n$ be the vector space of polynomials of degree at most $n$ (whose dimension is $s(d) := \binom{d+n}{d}$). For every $n \in \mathbb{N}$, let $\mathbb{N}^d_n := \{\alpha \in \mathbb{N}^d : |\alpha| = \sum_{i=1}^d \alpha_i \leq n\}$, and let $v_n(x) = (x^\alpha), \alpha \in \mathbb{N}^d$, be the vector of monomials of the canonical basis $(x^\alpha)$ of $\mathbb{R}[x]_n$. Given a closed set $\mathcal{X} \subseteq \mathbb{R}^n$, let $\mathcal{P}(\mathcal{X}) \subset \mathbb{R}[x]$ (resp. $\mathcal{P}_n(\mathcal{X}) \subset \mathbb{R}[x]_n$) be the convex cone of polynomials (resp. polynomials of degree at most $n$) that are nonnegative on $\mathcal{X}$. A polynomial $f \in \mathbb{R}[x]_n$ is written

$$x \mapsto f(x) = \sum_{\alpha \in \mathbb{N}^d} f_\alpha x^\alpha = \langle f, v_n(x) \rangle,$$

with vector of coefficients $f = (f_\alpha) \in \mathbb{R}^{s(n)}$ in the canonical basis of monomials $(x^\alpha)_{\alpha \in \mathbb{N}^d}$. For real symmetric matrices, let $\langle B, C \rangle := \text{trace}(B C)$ while the notation $B \succeq 0$ stands for $B$ is positive semidefinite (psd) whereas $B > 0$ stands for $B$ is positive definite (pd). Denote by $\mathcal{S}^n$ the space of real $n \times n$ symmetric matrices and $\mathcal{S}_+^n$ its subset of positive semidefinite matrices.

With a closed set $S \subset \mathbb{R}^d$, denote by $\mathcal{M}(S)$ the space of finite signed Borel measures on $S$, and $\mathcal{M}(S)_+ \subset \mathcal{M}(S)$ (resp. $\mathcal{P}(S)$) the convex cone of finite nonnegative Borel measures (resp. probability measures) on $S$. The support $\text{supp}(\mu)$ of a Borel measure $\mu$ on $\mathbb{R}^d$ is the smallest closed set $\Omega \subset \mathbb{R}^d$ such that $\mu(\mathbb{R}^d \setminus \Omega) = 0$.

Riesz linear functional. Given a sequence $\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}$ (in bold), its associated Riesz linear functional is the linear mapping $\phi : \mathbb{R}[x] \to \mathbb{R}$ (not in bold) defined
by:

\[
\phi_{\alpha} = \int_{\mathbb{R}^d} x^\alpha \, d\phi, \quad \forall \alpha \in \mathbb{N}^d.
\]

A sequence \( \phi \) has a representing measure if its associated Riesz linear functional \( \phi \) is a (positive) Borel measure on \( \mathbb{R}^d \), in which case,

\[
\phi_{\alpha} = \int_{\mathbb{R}^d} x^\alpha \, d\phi, \quad \forall \alpha \in \mathbb{N}^d.
\]

Given a sequence \( \phi = (\phi_{\alpha})_{\alpha \in \mathbb{N}^d} \) and a polynomial \( g \in \mathbb{R}[x] \), \( x \mapsto g(x) = \sum \gamma g_{\gamma} x^\gamma \), define the new sequence \( g \cdot \phi \) defined by

\[
(g \cdot \phi)_{\alpha} := \phi(x^\alpha g) = \sum_{\gamma \in \mathbb{N}^d} g_{\gamma} \phi_{\alpha+\gamma}, \quad \forall \alpha \in \mathbb{N}^d,
\]

and therefore its associated Riesz linear functional, denoted by \( g \cdot \phi \), satisfies

\[
g \cdot \phi(f) = \phi(g f), \quad \forall f \in \mathbb{R}[x].
\]

In particular, if \( \phi \) has a representing measure \( \phi \) and \( g \) is nonnegative, then the Riesz linear functional \( g \cdot \phi \) is a representing measure, i.e.,

\[
g \cdot \phi(f) = \phi(g f) = \int_{\mathbb{R}^d} f \, g \, d\phi, \quad \forall f \in \mathbb{R}[x].
\]

Moment matrix. The (degree-\( n \)) moment matrix associated with a sequence \( \phi = (\phi_{\alpha})_{\alpha \in \mathbb{N}^d} \) (or, equivalently, with the Riesz linear functional \( \phi \)), is the real symmetric matrix denoted \( M_n(\phi) \) (or \( M_n(\phi) \)) with rows and columns indexed by \( \mathbb{N}^d_n \), and whose entry \( (\alpha, \beta) \) is just \( \phi_{\alpha+\beta} \), for every \( \alpha, \beta \in \mathbb{N}^d_n \). So \( M_n(\phi) \) depends only on moments \( \phi_{\alpha} \) of degree at most \( 2n \). Alternatively, if one introduces the real symmetric matrices \( (B^1_\alpha) \subset \mathcal{S}^n(\mathbb{R}) \) defined by

\[
B^1_\alpha = \sum_{\alpha \in \mathbb{N}^d_{2n} \backslash \mathbb{N}^d_n} \phi_{\alpha} B^1_\alpha. \quad \forall x \in \mathbb{R}^d,
\]

then \( M_n(\phi) = \sum_{\alpha \in \mathbb{N}^d_{2n} \backslash \mathbb{N}^d_n} \phi_{\alpha} B^1_\alpha \). Moreover, if \( \phi \) has a representing measure \( \phi \) then \( M_n(\phi) \geq 0 \) because \( \langle f, M_n(\phi) f \rangle = \int f^2 \, d\phi \geq 0 \), for all \( f \in \mathbb{R}[x]_n \).

A measure whose all moments are finite, is moment determinate if there is no other measure with same moments.

Localizing matrix. With \( \phi \) as above and \( g \in \mathbb{R}[x] \) (with \( g(x) = \sum \gamma g_{\gamma} x^\gamma \)), the localizing matrix associated with \( \phi \) and \( g \) is the moment matrix \( M_n(g \cdot \phi) \) associated with the sequence \( g \cdot \phi \). That is, \( M_n(g \cdot \phi) \) is the real symmetric matrix with rows and columns indexed by \( \mathbb{N}^d_n \), and whose entry \( (\alpha, \beta) \) is just \( (g \cdot \phi)_{\alpha+\beta} \), that is, \( M_n(g \cdot \phi)(\alpha, \beta) = \sum \gamma g_{\gamma} \phi_{\alpha+\beta+\gamma} \), for every \( \alpha, \beta \in \mathbb{N}^d_n \).

Alternatively, letting \( d_g := \lceil \deg(g) / 2 \rceil \), and introducing the real symmetric matrices \( B^g_\alpha \in \mathcal{S}^n(\mathbb{R}), \alpha \in \mathbb{N}^d, \) defined by

\[
g(x) \, v_n(x) \, v_n(x)^T = \sum_{\alpha \in \mathbb{N}^d_{2(n+d_g)}} B^g_\alpha x^\alpha, \quad \forall x \in \mathbb{R}^d,
\]

one obtains \( M_n(g \cdot \phi) = \sum_{\alpha \in \mathbb{N}^d_{2(n+d_g)}} \phi_{\alpha} B^g_\alpha \).
If $\phi$ has a representing measure $\phi$ whose support is contained in the set $\{x : g(x) \geq 0\}$ then $M_n(g \cdot \phi) \geq 0$ for all $n$, because
\[
(f, M_n(g \cdot \phi)f) = g \cdot \phi(f^2) = \phi(f^2g) = \int f^2g \, d\phi \geq 0, \quad \forall f \in \mathbb{R}[x]_n.
\]

2.2. **SOS polynomials and quadratic modules.** A polynomial $f \in \mathbb{R}[x]$ is a Sum-of-Squares (SOS) if there exist $s \in \mathbb{N}$, and $f_1, \ldots, f_s \in \mathbb{R}[x]$, such that $f(x) = \sum_{k=1}^s f_k(x)^2$, for all $x \in \mathbb{R}^d$. Denote by $\Sigma[x]$ (resp. $\Sigma[x]_n$) the set of SOS polynomials (resp. SOS polynomials of degree at most $2n$). Of course every SOS polynomial is nonnegative. However the converse is not true.

Membership in $\Sigma[x]_n$. Checking whether a given polynomial $f$ is nonnegative on $\mathbb{R}^d$ is difficult whereas, and this is crucial for the Moment-SOS hierarchy, checking whether $f$ is SOS is much easier and can be done efficiently. Indeed let $f \in \mathbb{R}[x]_{2n}$ (for $f$ to be SOS its degree must be even), $x \mapsto f(x) = \sum_{\alpha \in \mathbb{N}^d} f_\alpha x^\alpha$. Then $f \in \mathbb{R}[x]_{2n}$ is SOS if and only if there exists a real symmetric matrix $X^T = X$ of size $s(n) = \binom{d+n}{d}$, such that:
\[
X \succeq 0, \quad f_\alpha = \langle X, B^\dagger_\alpha \rangle, \quad \forall \alpha \in \mathbb{N}^d_{2n},
\]
where the matrices $B^\dagger_\alpha$ have been introduced in (8). It turns out that (10) defines the feasible set of what is called a *semidefinite program*\(^3\) (in short, SDP).

Quadratic module. Introduce the constant polynomial $x \mapsto g_0(x) := 1$ for all $x \in \mathbb{R}^d$ (also denoted $g_0 = 1$). With a family $(g_1, \ldots, g_m) \subset \mathbb{R}[x]$ is associated the *quadratic module* $Q(g) (= Q(g_1, \ldots, g_m)) \subset \mathbb{R}[x]$ defined by:
\[
Q(g) := \left\{ \sum_{j=0}^m \sigma_j g_j : \sigma_j \in \Sigma[x], \; j = 0, \ldots, m \right\},
\]

and its degree-$2n$ truncated version
\[
Q_n(g) := \left\{ \sum_{j=0}^m \sigma_j g_j : \sigma_j \in \Sigma[x]_{n-d_j}, \; j = 0, \ldots, m \right\},
\]
where $d_j := \lceil \deg(g_j)/2 \rceil, \; j = 0, \ldots, m$. Observe that $Q_n(g) \subset \mathbb{R}[x]_{2n}$ because indeed in (12), $\deg(\sigma_j g_j) \leq 2n$, for all $j = 0, \ldots, m$. Obviously both $Q(g)$ and its truncated version $Q_n(g)$ are convex cones of $\mathbb{R}[x]$.

**Definition 2.1.** The quadratic module $Q(g)$ is said to be Archimedean if there exists $M > 0$ such that the quadratic polynomial $x \mapsto M - \|x\|^2$ belongs to $Q(g)$ (i.e., belongs to $Q_n(g)$ for some $n$).

If $Q(g)$ is Archimedean then necessarily, the set
\[
S := \{ x \in \mathbb{R}^d : g_j(x) \geq 0, \quad j = 1, \ldots, m \}
\]
is compact but the reverse is not true. The Archimedean condition depends on the *representation* of $S$ and can be seen as an *algebraic certificate* that $S$ is compact.

---

\(^3\)A semidefinite program (SDP) is a convex and conic optimization problem which can be solved (up to fixed arbitrary precision) in time polynomial in its input size; see e.g. [3] and also [102].
Dual cone. The dual cone $Q^*_n(g)$ of $Q_n(g)$ is the convex cone of $\mathbb{R}^{n(2n)}$ defined by:

$$Q^*_n(g) = \{ \phi \in \mathbb{R}^{n(2n)} : M_{n-d_j}(g_j \cdot \phi) \geq 0, j = 0, \ldots, m \},$$

where $M_{n}(g_j \cdot \phi)$ is the localizing matrix associated with the polynomial $g_j$ and the sequence $\phi$, defined in Section 2.1.

For more details on the above notions of moment and localizing matrix, quadratic module, as well as their use in potential applications, the interested reader is referred to [76] and [60]. As we will see, both convex cones $Q_n(g)$ and $Q^*_n(g)$ play a crucial role in the Moment-SOS hierarchy of lower bounds.

2.3. Certificates of positivity (Positivstellensätze). Below we describe particular certificates of positivity which are important because they provide a theoretical justification (or rationale) behind convergence of the so-called SDP- and LP-relaxations for global optimization. In particular, the one below in (15) is at the core of the Moment-SOS hierarchy of lower bounds.

**Theorem 2.2** ([113]). Let $S \subset \mathbb{R}^d$ be as in (13) and assume that $Q(g)$ is Archimedean.

(i) If a polynomial $f \in \mathbb{R}[x]$ is (strictly) positive on $S$ then $f \in Q(g)$, that is,

$$f = \sum_{j=0}^{m} \sigma_j g_j,$$

for some SOS polynomials $\sigma_j \in \Sigma[x]$, $j = 0, \ldots, m$ (and so $f \in Q_n(g)$ for some $2n \geq \deg(f)$).

(ii) A sequence $\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^m} \subset \mathbb{R}$ has a representing Borel measure on $S$ if and only if $\phi(f^2 g_j) \geq 0$ for all $f \in \mathbb{R}[x]$, and all $j = 0, \ldots, m$. Equivalently, if and only if $M_n(g_j \cdot \phi) \geq 0$ for all $j = 0, \ldots, m$, and all $n \in \mathbb{N}$.

In fact Theorem 2.2 is a refinement of an earlier theorem by Schmüdgen two years before.

**Theorem 2.3** ([116]). Let the basic semi-algebraic set $S \subset \mathbb{R}^d$ in (13) be compact.

(i) If a polynomial $f \in \mathbb{R}[x]$ is (strictly) positive on $S$ then

$$f = \sum_{\alpha \in \{0,1\}^m} \sigma_\alpha g_1^{a_1} \cdots g_m^{a_m},$$

for some SOS polynomials $\sigma_\alpha \in \Sigma[x]$, $\alpha \in \{0,1\}^m$.

(ii) A sequence $\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^m} \subset \mathbb{R}$ has a representing Borel measure on $S$ if and only if $\phi(f^2 g_1^{a_1} \cdots g_m^{a_m}) \geq 0$ for all $f \in \mathbb{R}[x]$, and all $\alpha \in \{0,1\}^m$. Equivalently, if and only if $M_n(g_1^{a_1} \cdots g_m^{a_m} \cdot \phi) \geq 0$ for all $\alpha \in \{0,1\}^m$, and all $n \in \mathbb{N}$.

Observe that (15) is of the same flavor as (16) but much simpler as it involves only $m+1$ SOS polynomials $\sigma_j \in \Sigma[x]$ (as opposed to $2^m$ SOS $\sigma_\alpha$ in (16)). On the other hand, in Theorem 2.3 the only condition is that the set $S$ is compact whereas in Theorem 2.2 one also requires that the quadratic module $Q(g)$ is Archimedean (an additional condition on the representation of $S$).

The reader may have noticed that Theorem 2.2 and Theorem 2.3 have two facets (i) and (ii): The former is the algebraic facet (certificate of positivity) while the latter with a real analysis flavor is related to the $S$-moment problem. Both facets
are a nice illustration of the duality between moments and positive polynomials.

We next provide a Nichtnegativstellensatz (a theorem of nonnegativity) of the author [61] which is instrumental in proving convergence of the hierarchy of upper bounds in Section 5.

**Theorem 2.4.** Let $S \subset \mathbb{R}^d$ be a compact set (not necessarily basic semi-algebraic), and let $\phi$ be a Borel measure with $\text{supp}(\phi) = S$, and with moment sequence $\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}$. If $f \in \mathbb{R}[x]$ then

$$f \geq 0 \text{ on } S \iff M_n(f \cdot \phi) \geq 0, \quad \forall n \in \mathbb{N}. \quad (17)$$

Theorem 2.4 states that to decide whether $f$ is nonnegative on $S$, one must check whether countably many Linear Matrix Inequalities (LMI) $M_n(f \cdot \phi) \geq 0, n \in \mathbb{N}$, hold. Each constraint $M_n(f \cdot \phi) \geq 0$ is indeed an LMI on the coefficients of the polynomial $f$ because each entry of $M_n(f \cdot \phi)$ is linear in the coefficients $f$ of $f$. Therefore identifying $f \in \mathbb{R}[x]$ with its vector $f \in \mathbb{R}^{s(k)}$ of coefficients, for each $n \in \mathbb{N}$, the convex cone $\Omega_n \subset \mathbb{R}[x]_k$ defined by

$$\Omega_n := \{ f \in \mathbb{R}^{s(k)} : M_n(f \cdot \phi) \geq 0 \},$$

is a spectrahedron that contains the convex cone $\mathcal{P}_k(S)$ of polynomials of degree at most $k$ that are nonnegative on $S$. In addition $\Omega_{n+1} \subset \Omega_n$ for all $n$, so that the sequence $(\Omega_n)_{n \in \mathbb{N}}$ of outer approximations of $\mathcal{P}_k(S)$ is monotone non increasing. Moreover, it converges to $\mathcal{P}_k(S)$, i.e., $\bigcap_{n \in \mathbb{N}} \Omega_n = \mathcal{P}_k(S)$.

So in contrast to Theorem 2.2 and 2.3, Theorem 2.4 is valid for arbitrary compact sets $S \subset \mathbb{R}^d$ and nonnegative (as opposed to positive) polynomials on $S$. On the other hand, its practical use to over-approximate the convex cone $\mathcal{P}_k(S)$ by $\Omega_n$, requires knowledge of moments $\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}$ of a measure $\phi$ with $\text{supp}(\phi) = S$. This is only possible for specific sets and measures. Examples of such special sets include the unit box, unit Euclidean ball, unit sphere, canonical simplex, discrete cube $\{-1, 1\}^d$, and their image by an affine transformation.

LP-based certificate. We next introduce another certificate of positivity which does not use SOS. Given $g_1, \ldots, g_m \in \mathbb{R}[x]$, introduce the notation $g^\alpha \in \mathbb{R}[x]$, and $(1 - g^\alpha) \in \mathbb{R}[x]$, with:

$$x \mapsto g^\alpha(x) := g_1(x)^{\alpha_1} \cdots g_m(x)^{\alpha_m}, \quad \forall x \in \mathbb{R}^d,$$

$$x \mapsto (1 - g^\alpha(x)) := (1 - g_1(x))^{\alpha_1} \cdots (1 - g_m(x))^{\alpha_m}, \quad \forall x \in \mathbb{R}^d,$$

and the convex cone $\mathcal{L}_n(g) \subset \mathbb{R}[x]$ defined by:

$$\mathcal{L}_n(g) := \{ \sum_{(\alpha, \beta) \in \mathbb{Z}_{\geq 0}^m} c_{\alpha \beta} g^\alpha (1 - g^\beta) : c = (c_{\alpha \beta}) \geq 0 \} \quad (18)$$

**Theorem 2.5** ([48, 49, 133]). Let $S \subset \mathbb{R}^d$ as in (13) be compact and such that (possibly after scaling) $0 \leq g_j(x) \leq 1$ for all $x \in S$, $j = 1, \ldots, m$. Assume also that $[1, g_1, \ldots, g_m]$ generates $\mathbb{R}[x]$. 

(i) If a polynomial \( f \in \mathbb{R}[x] \) is (strictly) positive on \( S \) then \( f \in \mathcal{L}_n(g) \) for some \( n \), that is:

\[
    f = \sum_{(\alpha, \beta) \in \mathbb{N}^{2m}} c_{\alpha \beta} g^\alpha (1 - g)^\beta.
\]

for some nonnegative vector \( c = (c_{\alpha \beta})_{(\alpha, \beta) \in \mathbb{N}^{2m}} \).

(ii) A sequence \( \phi = (\phi_x)_{x \in S} \subset \mathbb{R} \) has a representing Borel measure on \( S \) if and only if \( \phi (g^\alpha (1 - g)^\beta) \geq 0 \) for all \( \alpha, \beta \in \mathbb{N}^m \).

Remark 2.6. Interestingly, as for Theorems 2.2-2.3, Theorem 2.5 has also two facets. The algebraic facet (i) is concerned with representation of polynomials that are positive on \( S \), while facet (ii) is concerned with the \( S \)-moment problem in real analysis. Hence Theorem 2.5 is another illustration of the duality between polynomials positive on \( S \) and the \( S \)-moment problem.

2.4. Practical implementation of Positivstellensätze via SDP or LP. In addition to being interesting in their own right, Theorem 2.2(i) and (2.5)(i) have another distinguishing feature. Both have a practical implementation that allows to perform interesting computations. Indeed:

- Testing membership in \( Q_n(g) \) is just solving a single SDP, whereas
- testing membership in \( \mathcal{L}_n(g) \) is just solving a single Linear Program (LP).

Testing membership in \( Q_n(g) \) is crucial for a practical and efficient implementation of the Moment-SOS hierarchy. Fortunately it can be done via solving an SDP. Namely, let \( f \in \mathbb{R}[x]_k \) and recall that \( d_j = \lceil \deg(g_j)/2 \rceil, j = 0, \ldots, m \). Then testing whether \( f \in Q_n(g) \) (with necessarily \( 2n \geq k \)) reduces to solving:

\[
    f_\alpha = \sum_{j=0}^m \langle X_j, B_{\alpha j}^g \rangle, \quad \forall \alpha \in \mathbb{N}_d^{2n}; \quad X_j \in \mathcal{S}^{n-d_j};
\]

\[
    X_j \succeq 0, \quad j = 0, \ldots, m.
\]

where the real symmetric matrices \( B_{\alpha j}^g \in \mathcal{S}^{n-d_j} \) are defined in (9) (here with \( n-d_j \) instead of \( n \)). Each real symmetric matrix \( X_j \) is a Gram matrix of a polynomial \( \sigma_j, j = 0, \ldots, m \). Next, (20) are linear equality constraints on the unknown entries of \( X_j \), while (21) is a positive semidefinite constraint on \( (X_j)_{j=0}^m \) to ensure that every \( \sigma_j \) is an SOS. (In (20), \( f_\alpha = 0 \) whenever \( k < |\alpha| \leq 2n \) because \( f \in \mathbb{R}[x]_k \).)

Observe that multiplying (20) by \( x^\alpha \) and summing up yield

\[
    f(x) = \sum_{\alpha \in \mathbb{N}_d^{2n}} f_\alpha x^\alpha = \sum_{j=0}^m \langle X_j, \sum_{\alpha \in B_{\alpha j}^g} B_{\alpha j}^g x^\alpha \rangle
\]

\[
    = \sum_{j=0}^m \langle X_j, v_{n-d_j}(x)v_{n-d_j}(x)^T \rangle g_j(x) \quad \text{[see (9)]}
\]

\[
    = \sum_{j=0}^m v_{n-d_j}(x)^T X_j v_{n-d_j}(x) g_j(x) \quad \text{[\( \sigma_j(x) \)}
\]

Hence checking whether (20)-(21) has a solution reduces to solving an SDP.
Membership in $\mathcal{L}_n(g)$. Obviously testing whether some polynomial $f \in \mathbb{R}[x]_k$ is in $\mathcal{L}_n(g)$, reduces to solving a linear programming problem (LP). Indeed, with $n$ such that $s := (\max_j \deg(g_j))^n \geq k$, it amounts to find a nonnegative vector $c = (c_{\alpha, \beta})$, $(\alpha, \beta) \in \mathbb{N}_n^{2m}$, such that

$$f_\gamma = \left( \sum_{(\alpha, \beta) \in \mathbb{N}_n^{2m}} c_{\alpha, \beta} \prod_{j=1}^m g_j(x)^{\alpha j} (1 - g_j(x))^{\beta j} \right), \quad \forall \gamma \in \mathbb{N}_d,$$

and with $f_\gamma = 0$ whenever $|\gamma| > k$. Clearly, the above constraints are linear in the unknown coefficients $c_{\alpha, \beta} \geq 0$, and so checking existence of such a vector $c \geq 0$ reduced to solving a linear programming problem (LP).

2.5. Notes and sources. Most of the material is from [60, 63]. A good reference for exhaustive results on positive polynomials and moment problems is [76, 85, 111, 117, 98, 44]; see also [15] for related material on convex algebraic geometry.

Section 2.3. Theorem 2.4 is from [61, 62]. Interestingly, it is also valid for some non-compact sets like e.g. the positive orthant $\mathbb{R}^d_+$ or even the whole space $\mathbb{R}^d$. For the former the measure $\phi$ can be chosen to be the exponential measure $d\phi = \exp(\sum_i x_i)dx$ while for the latter one may choose the gaussian measure $d\phi = \exp(-||x||^2/2)dx$. In both cases one obtains a monotone sequence $(\Omega_n)_{n \in \mathbb{N}}$ of outer-approximations which converges to $\mathbb{R}_+$ and $\mathbb{R}^d$ respectively.

Section 2.4. It is worth mentioning that other certificates of positivity (via convex cones of positive polynomials) have been also defined to overcome (or at least mitigate) the computational burden associated with testing membership in $Q_n(g)$ in (20)-(21) (via semidefinite programing). For instance, membership in corresponding alternative convex cones can be checked by linear programming for DSOS and second-order cone programing for SDSOS [1]; see also [81]. An alternative described in Section 3.8 is to consider a sparse-version of Theorem 2.2 when $P$ exhibits some sparsity pattern. As we will see, it yields a sparsity-adapted version of the Moment-SOS hierarchy which can handle non-convex POPs with more than a thousand variables; see also [78].

3. The Moment-SOS Hierarchy in Optimization

Consider the polynomial optimization problem (POP) $P$ in (1), and assume that its associated feasible set $S \subset \mathbb{R}^d$ is compact.

3.1. The Moment-SOS hierarchy. The underlying principle behind the Moment-SOS Hierarchy is quite simple and proceeds in two steps.

When viewing $P$ in its equivalent formulation (3) (real algebraic glasses).

step 1:: One replaces the hard constraint “$f - \lambda \geq 0$ on $S$” with the equivalent constraint $f \in Q(g)$ (with $Q(g)$ being the quadratic module defined in (11)).
Indeed
\[ f^* = \sup \left\{ \lambda : f - \lambda \geq 0 \text{ on } S \right\} = \sup \left\{ \lambda : f - \lambda > 0 \text{ on } S \right\} \]
where the second equality follows from Theorem 2.2(i) if the quadratic module \( Q(g) \) is Archimedean. However, (22) is still an infinite dimensional problem.

**Step 2:** Next, with \( n_0 := \max \left[ \frac{\deg(f)}{2}, \max_j \frac{\deg(g_j)}{2} \right] \), and \( n \geq n_0 \), one replaces (22) with the more restrictive constraint
\[ \tau_n^* = \sup \left\{ \lambda : f - \lambda \in Q_n(g) \right\} \quad (n \geq n_0) \]
so that \( f^* \geq \tau_n^* \) for all \( n \geq n_0 \). A crucial feature of (24) is to be a finite-dimensional convex optimization problem, and more precisely a semidefinite program. Therefore (24) can be solved (up to arbitrary fixed precision) in time polynomial in its input size.

So in solving (23) for increasing values of \( k \in \mathbb{N} \), one obtains a monotone non decreasing sequence \( (\tau_n^*)_{n \geq n_0} \) of lower bounds on the global minimum of \( f^* \) of \( P \).

When viewing \( P \) in its equivalent formulation (4) (real analysis glasses). First observe that since \( f \in \mathbb{R}[x] \),
\[ \int_S f \, d\phi = \sum_{\sigma \in \Sigma^d} f_\sigma \int_S x^\sigma \, d\phi = \sum_{\alpha \in \mathbb{N}^d} f_\alpha \phi_\alpha. \]
Therefore
\[ f^* = \inf_{\phi \in M(S)_+} \left\{ \int_S f \, d\phi : \phi(S) = 1 \right\} \]
\[ = \inf_{\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}} \left\{ \langle f, \phi \rangle : \phi_0 = 1 ; \phi \text{ has a representing measure supported on } S \right\}. \]

Again one proceeds in two steps:

**Step 1:** If \( Q(g) \) is Archimedean then by invoking Theorem 2.2(ii), one may replace the constraint “\( \phi \) has a representing measure supported on \( S \)” with the equivalent constraint “\( M_n(g_j \cdot \phi) \geq 0 \) for all \( j = 0, \ldots, m \), and all \( n \in \mathbb{N} \)”.
However the optimization problem
\[ f^* = \inf_{\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}} \left\{ \langle f, \phi \rangle : \phi_0 = 1 ; M_n(g_j \cdot \phi) \geq 0, \quad j = 0, \ldots, m, \quad n \in \mathbb{N} \right\} \]
is still infinite-dimensional.

**Step 2:** Next, one then replaces (25) with its truncated versions
\[ \tau_n = \inf_{\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}} \left\{ \langle f, \phi \rangle : \phi_0 = 1 ; M_{n-d_j}(g_j \cdot \phi) \geq 0, \quad j = 0, \ldots, m \right\}, \]
where \( n \geq n_0 \) with \( n_0 := \max[\lceil \deg(f)/2 \rceil, \max_j[\deg(g_j)/2]] \). For each fixed \( n \), (26) is a finite-dimensional semidefinite program.

Clearly, \( \tau_n \leq \tau_{n+1} \leq f^* \) for all \( n \geq n_0 \), and therefore in solving (26) for increasing values of \( n \in \mathbb{N} \), one obtains a monotone non decreasing sequence \( (\tau_n)_{n \geq n_0} \) of lower bounds on the global minimum of \( f^* \) of \( P \).

In fact the semidefinite program (24) is the dual of the semidefinite program (26), and by weak duality in convex optimization,

\[
\tau^*_n \leq \tau_n \leq f^*, \quad \forall n \geq n_0.
\]

As it is clear from its formulation, (26) is a semidefinite relaxation of \( P \) as its constraints are only necessary conditions for \( \phi \) to have a representing measure \( \phi \) on \( S \). We call (26) a Moment-relaxation of \( P \).

On the other hand, its dual (24) is a reinforcement (or strengthening) of \( P \) (viewed as the maximization problem (3)) as one has replaced “\( f - \lambda \geq 0 \) on \( S \)” with the sufficient condition “\( f - \lambda \in Q_n(\mathbb{R}) \)”.

We call (24) an SOS-reinforcement (or SOS-strengthening) of \( P \), whence the name “Moment-SOS hierarchy” for (26)-(24). In both cases one obtains a lower bound \( \tau_n \) (resp. \( \tau^*_n \)) on \( f^* \).

When \( \tau_n = f^* \) (resp. \( \tau^*_n = f^* \)) for some \( n \), one says that the degree-\( n \) Moment-relaxation (26) (resp. the degree-\( n \) SOS-reinforcement (24)) of \( P \) is exact. In addition, if \( \tau_n = f^* \) and an optimal solution \( \phi^* \) of (26) satisfies \( \text{rank}(M_n(\phi^*)) = 1 \) then \( \phi^* \) is nothing less than the vector of moments up to degree \( 2n \) of the Dirac measure \( \delta_{\{x^*\}} \) at a global minimizer \( x^* \in S \). In particular the subvector \( \phi^*(x_i)_{i=1,\ldots,d} \) of first-order moments is just the vector \( x^* \).

In summary, the ultimate goal of the moment-relaxation (26) is to obtain at some step \( n \), an optimal solution \( \phi^* \in \mathbb{R}^{s(2n)} \) which is the vector of moments (up to degree \( 2n \)) of the Dirac measure \( \delta_{\{x^*\}} \) at a minimizer \( x^* \in S \).

When \( P \) has a unique global minimizer \( x^* \in S \), this happens generically; in case of finely many global minimizers it will happen generically that at some step \( n \), \( \phi^* \) is be the vector of moments of a convex combination of Dirac measures at such global minimizers; see Theorem 3.3 and Lemma 3.4 below.

**Remark 3.1.** (a) As just explained above, it is more appropriate to call (24) an SOS-reinforcement of \( P \) instead of an SOS-relaxation of \( P \) as is sometimes written in the literature. Of course, it is also the dual of the Moment-relaxation (26) of \( P \).

(Relaxing in the primal is equivalent to reinforcing in the dual.)

(b) We call (3) (resp. (26)) a primal formulation (resp. a primal semidefinite relaxation) of \( P \) because in solving \( P \) one is mainly interested in an optimal solution \( x^* \in S \) (a global minimizer of \( P \)), and so the primary variable of interest is \( x \in S \subset \mathbb{R}^d \). If \( x^* \in S \) is an optimal solution of \( P \) then \( \phi^* = ((x^*)^\alpha)_{\alpha \in \mathcal{L}_d} \) is an optimal solution of (25).

Then (23) is the dual of the semidefinite relaxation (26), and one will see that indeed when \( \tau^*_n = f^* \) for some \( n \) and (23) has an optimal solution \( \sigma^*_j \in \Sigma [x]_{k-d_j}, j = 0, \ldots, m \), then \( \sigma^*_j(x^*) = \lambda^*_j \geq 0 \) for all \( j = 1, \ldots, m \), where the \( \lambda^*_j \) are optimal KKT-Lagrange multipliers associated with a global minimizer \( x^* \in S \).
Computational considerations. The Moment-relaxation (26) is a semidefinite program with
- \( \binom{d+2n}{d} \) variables \( \phi_{\alpha} \).
- \( m + 1 \) moment-localizing matrices of size \( \binom{d+n-d_j}{d} \), \( j = 0, \ldots, m \),

while the SOS-strengthening (24) is a semidefinite program with
- \( 1 + \sum_{j=0}^{m} \binom{d+2n-2d_j}{d} \) variables \( (\lambda, (\sigma_0)_\alpha, \ldots, (\sigma_m)_\alpha) \)
- \( m + 1 \) semidefinite constraints for matrices of size \( \binom{d+n-d_j}{d} \), \( j = 0, \ldots, m \).
- \( \binom{d+2n}{d} \) equality constraints.

For fixed dimension \( d \), the size of matrices and the number of variables in the primal and dual semidefinite programs are polynomial in \( d \). Therefore in principle they can be solved efficiently (up to arbitrary fixed precision) in time polynomial in their input size\(^4\). However, in view of their non-modest size and the current status of semidefinite solvers, such semidefinite programs can be solved only for POPs of modest dimension \( d \) and small degree-\( n \) relaxation. So in its canonical form (26)-(24), the Moment-SOS hierarchy is limited to POPs of modest dimension. However and fortunately:

- Practice reveals that finite convergence often occurs at low degree \( n \).
- As is often the case for many POP of large dimension \( d \), some sparsity pattern and/or symmetries are present. It turns out that they can be exploited to define appropriate Moment-relaxations (resp. SOS-strengthenings) of \( P \) whose size is still compatible with current SDP-solvers; see Section 3.8 for more details.
- Another possibility is to neglect the costly interior-point methods of SDP solvers and solve the semidefinite programs (24) and (26) by first-order methods; see e.g. [144], [80].

More details are provided in Section 3.8.

3.2. Convergence of the Moment-SOS Hierarchy. Observe that if \( S \subset \mathbb{R}^d \) is compact then \( S \) is contained in the Euclidean ball of radius \( M \) for some \( M > 0 \), and in many applications \( M \) is known. Therefore the quadratic constraint \( M^2 - \|x\|^2 \geq 0 \) is redundant when \( x \in S \).

For a practical implementation of the Moment-SOS hierarchy, it is always recommended to indeed add the redundant constraint \( g_1(x) := M^2 - \|x\|^2 \geq 0 \) in the definition (13) of \( S \). Moreover, to avoid possible numerical ill-conditioning if \( M \) is large, it is even recommended to scale problem \( P \) in such a manner that \( S \subset B_1 := \{x : \|x\| \leq 1\} \) so that \( g_1(x) = 1 - \|x\|^2 \). Hence:

**Assumption 3.2.** \( S \subset \mathbb{R}^d \) defined in (13) is compact with \( x \mapsto g_1(x) = 1 - \|x\|^2 \) (so that \( S \subset B_1 \)).

The reason to do that is because under Assumption 3.2, the quadratic module \( Q(g) \) in (11) is guaranteed to be Archimedean, a crucial property for convergence

\(^4\)More precisions can be found in e.g. [102]
of the Moment-SOS hierarchy. (In general proving that $Q(g)$ is Archimedean may not be trivial.)

**Theorem 3.3.** With $S \subset \mathbb{R}^d$ as in (13), let Assumption 3.2 hold and let $\tau_n$ (resp. $\tau^*_n$) be as in (26) (resp. (24)) for all $n \geq n_0$. Then:

(a) $\tau^*_n = \tau_n$ for all $n \geq n_0$, and for every $n \geq n_0$, the semidefinite relaxation (26) has an optimal solution $\phi^n = (\phi^n_\alpha)_{\alpha \in \mathbb{N}_2^d}$. Moreover, both sequences $(\tau^*_n)_{n \geq n_0}$ and $(\tau_n)_{n \geq n_0}$ are monotone non decreasing, and

$$\lim_{n \to \infty} \tau^*_n = \lim_{n \to \infty} \tau_n = f^*.$$  

(b) With $\phi^n$ an optimal solution of (26), let $\nu := \max_{j=1,...,m} \deg(g_j)/2$. If

$$\text{rank} \ M_t(\phi^n) = \text{rank} \ M_{t-v}(\phi^n) \ (=: s),$$  

for some $v \leq t \leq n$, then $\tau^*_n = \tau_n = f^*$ and from the vector $\phi^n$ one may extract $x^*(\ell) \in S$, $\ell = 1, \ldots, s$, where each $x^*(\ell) \in S$ is a global minimizer of $P$, that is, $f(x^*(\ell)) = f^*$, $\ell = 1, \ldots, s$.

(c) If $\text{int}(S) \neq \emptyset$ then for every $n \geq n_0$, the SOS-strengthening (24) of $P$ has an optimal solution $(\tau^*_n, \sigma^*_0, \ldots, \sigma^*_m)$.

Convergence of minimizers. Theorem 3.3 states that the sequence $(\tau_n)_{n \geq n_0}$ of optimal values converges to the global minimum $f^*$ of $P$ as the degree $n$ increases and moreover extraction of minimizers is also obtained if the degree-$n$ moment-relaxation is exact ($\tau_n = f^*$) and the flat extension condition (29) holds. But what about the sequence of minimizers $(\phi^n)_{n \geq n_0}$ in case when the convergence is only asymptotic (as opposed to finite)?

**Lemma 3.4.** Let the sequence $(\phi^n)_{n \geq n_0}$ with $\phi^n = (\phi^n_\alpha)_{\alpha \in \mathbb{N}_2^d}$, be as in Theorem 3.3(a). If $x^* \in S$ is the unique global minimizer of $P$ then

$$\lim_{n \to \infty} \phi^n_\alpha = \lim_{n \to \infty} \phi^n(x_\alpha^*) = (x^*)^\alpha, \quad \forall \alpha \in \mathbb{N}^d.$$  

In particular $\lim_{n \to \infty} \phi^n(x_i) = x_i^*$ for every $i = 1, \ldots, d$.

So in case when $P$ has a unique global minimizer and convergence of the Moment-relaxation (26) is only asymptotic (as opposed to finite), Lemma 3.4 states that the vector of degree-1 moments $(\phi^n(x_i))_{i=1,...,d}$ converges to the unique global minimizer $x^* \in S$ as $n$ increases.

Notice that (30) is also interesting even if finite convergence takes place at some $n$ because one may already obtain a good approximation of $x^* \in S$ from the degree-1 moments of $\phi^t$ for $t < n$.

Equality constraints. Of course in (13) one may tolerate equality constraints $g_j(x) \geq 0$ and $g_{j+1}(x) \geq 0$ with $g_{j+1} = -g_j$, $j \in J$, for some subset $J \subset \{1, \ldots, m\}$, in which case we simply write $g_j(x) = 0$, $j \in J$ (and remove the constraint $g_{j+1} \geq 0$). The resulting modifications are as follows:

- In (24) the unknown SOS weight $\sigma_j \in \Sigma[x]_{k-d_j}$ is now a polynomial in $\mathbb{R}[x]_{2(r-d_j)}$ and not an SOS anymore.
- In (26) the PSD constraint $M_{n-d_j}(g_j \cdot \phi) \geq 0$ now reads as the equality constraints $M_{n-d_j}(g_j \cdot \phi) = 0$ on the variables $(\phi_\alpha)$. 

Theorem 3.3(a)-(b) remains valid, whereas Theorem 3.3(c) needs some adjustment since \( \text{int}(S) = \emptyset \). For instance, if the ideal \( (g_j)_{j \in J} \subset \mathbb{R}[x] \) generated by the polynomials \( g_j \)'s associated with the equality constraints, is real radical, then for \( n \) sufficiently large, the SOS-strengthening (24) of \( P \) has an optimal solution \( (\tau_n^+, \sigma_0^n, \ldots, \sigma^n_m) \).

**Pseudo-boolean case.** An important case is when \( S \subset \{-1, 1\}^d \) (or equivalently, \( \{0, 1\}^d \) after a simple linear transformation), that is, \( J = \{1, \ldots, d\} \) and

\[
S = \{ x \in \mathbb{R}^d : x_j^2 - 1 = 0, \ j \in J; \ g_j(x) \geq 0, \ j \notin J \},
\]

of which the celebrated Maxcut problem is a particular case (no inequality constraint). Then the ideal \( \langle x_j^2 - 1 \rangle_{j \in J} = \langle x_1^2 - 1, \ldots, x_d^2 - 1 \rangle \) is indeed real radical and Theorem 3.3 applies. Of course in this case it follows that \( \tau_n = f^* \) whenever \( n \geq d + \max_j d_j \), and therefore the semidefinite relaxation (26) is not interesting as it contains \( 2^d \) variables \( \phi_k \). But the interest of Theorem 3.3 is that (29) may take place for \( n \ll d \). For instance in most random instances of Maxcut problems with \( d = 11 \), one observes \( f^* = \tau_2 \) (and even \( f^* = \tau_1 \) in several cases).

### 3.3. A global optimality-condition for polynomial optimization.

Theorem 3.3(a) guarantees that asymptotically as \( n \) increases, one recovers the global optimum \( f^* \), and moreover by Theorem 3.3(b), finite convergence takes place whenever the so-called flatness condition (29) holds at some degree \( n \). In the latter case we can say more. Indeed and remarkably, one is able to provide a global optimality-condition for non-convex POPs, of the same flavor as the celebrated KKT-optimality conditions for convex optimization, and under the same second-order sufficiency condition.

One first recalls the well-known standard first-order necessary and second-order sufficient KKT-optimality conditions in non-linear programming (NLP).

**First-order necessary KKT-optimality conditions.** With \( S \) as in (13), let \( x^* \in S \) be a local minimizer of \( P \), and let \( I(x^*) := \{ j \in \{1, \ldots, m\} : g_j(x^*) = 0 \} \) be the set of active constraints at \( x \in S \). With \( \mathbb{S}^{d-1} := \{ x \in \mathbb{R}^d : \|x\| = 1 \} \), let \( (x^*)^\perp := \{ u \in \mathbb{S}^{d-1} : (u, \nabla g_j(x^*)) = 0, \ \forall j \in I(x^*) \} \).

If the gradients \( \nabla g_j(x^*) \), \( j \in I(x^*) \), are linearly independent, there exists \( \lambda^* \in \mathbb{R}^m_+ \) such that

\[
\nabla f(x^*) - \sum_{j=1}^m \lambda_j^* \nabla g_j(x^*) = 0; \quad \lambda_j^* g_j(x^*) = 0, \ j = 1, \ldots, m.
\]

Moreover, strict complementarity holds if \( \lambda_j^* > 0 \) whenever \( g_j(x^*) = 0 \). Next, observe that if in addition \( f \) and \( -g_j \) are convex, then the Lagrangian

\[
x \mapsto L(x) := f(x) - f^* - \sum_{j=1}^m \lambda_j^* g_j(x), \quad \forall x \in \mathbb{R}^d,
\]

is convex, nonnegative, and satisfies \( \nabla L(x^*) = 0 \). Hence \( x^* \) is also a global minimizer of \( L \) on the whole space \( \mathbb{R}^d \), and \( L(x) \geq L(x^*) = 0 \) for all \( x \in \mathbb{R}^d \). This is a very strong property of the convex case.
Second-order sufficient KKT-optimality condition holds at a local minimizer \( x^* \in S \) of \( \mathbf{P} \), if (i) \((32)\) and strict complementarity hold at \((x^*, \lambda^*)\), and (ii) in addition,

\[
(33) \quad (\mathbf{u}, \nabla^2 f(x^*) - \sum_{j=1}^{m} \lambda_j^* \nabla^2 g_j(x^*)) > 0, \quad \forall \mathbf{u} \in (x^*)^\perp.
\]

If \((32)\), strict complementarity and \((33)\) hold at a global minimizer \( x^* \in S \) of \( \mathbf{P} \), then one obtains a remarkable certificate of global optimality.

**Theorem 3.5** (Certificate of global optimality). With \( S \) as in \((13)\), let \( x^* \in S \) be a global minimizer of \( \mathbf{P} \), and assume that:

(i) The gradients \( \nabla g_j(x^*) \), \( j \in I(x^*) \), are linearly independent (so that \((32)\) holds for some \( \lambda^* \in \mathbb{R}_+^n \)) and strict complementarity holds at \((x^*, \lambda^*)\).

(ii) Second-order sufficient condition \((33)\) holds at \((x^*, \lambda^*)\).

Then there exists \( n \in \mathbb{N} \) such that the SOS-strengthening \((24)\) is exact, i.e.:

\[
(34) \quad f(x) - f^* = \sum_{j=0}^{m} \sigma_j^*(\mathbf{x}) g_j(\mathbf{x}), \quad \forall \mathbf{x} \in \mathbb{R}^d;
\]

\[
(35) \quad \sigma_j^*(\mathbf{x}^*) g_j(\mathbf{x}^*) = 0, \quad j = 0, \ldots, m,
\]

for some SOS polynomials \( \sigma_j^* \in \Sigma[\mathbf{x}]_{n-d_j} \). Moreover, let \( \hat{\lambda} = (\hat{\lambda}_j) \in \mathbb{R}_+^n \) with \( \hat{\lambda}_j := \sigma_j^*(\mathbf{x}^*) \), \( j = 1, \ldots, m \). Then the couple \((x^*, \hat{\lambda}) \in S \times \mathbb{R}_+^m\) satisfies \((32)\) and \((33)\).

As an immediate consequence of Theorem 3.5, finite convergence of the Moment-SOS hierarchy takes place at degree-\( n \), that is \( \tau_n^* = \tau_n = f^* \).

**Remark 3.6.** We claim that Theorem 3.5 which provides an algebraic certificate of global optimality, is the perfect analogue for non-convex polynomial optimization of the KKT-optimality conditions for convex optimization. Indeed if \( f \) and \(-g_j\) are all convex, then any local optimizer \( x^* \in S \) is a global minimizer and then \((32)\) implies

\[
(36) \quad \mathbf{x} \mapsto L(\mathbf{x}) = f(\mathbf{x}) - f^* - \sum_{j=1}^{m} \lambda_j^* g_j(\mathbf{x}) \geq 0, \quad \forall \mathbf{x} \in \mathbb{R}^d;
\]

\[
(37) \quad L(x^*) = 0.
\]

But this of course is valid because \( f \) and \(-g_j\) are convex, a very specific case. In general a global minimizer \( x^* \in S \) is not a global minimizer of the Lagrangian \( L \) on \( \mathbb{R}^d \).

On the other hand Theorem 3.5 states that if \( x^* \in S \) is a global minimizer then under the standard second-order sufficient KKT-optimality condition in NLP, \( x^* \) is also a global minimizer of the extended Lagrangian \( \hat{L} := f - f^* - \sum_{j=1}^{m} \sigma_j^* g_j \) over the whole space \( \mathbb{R}^d \). Indeed,

\[
(38) \quad \hat{L}(\mathbf{x}) = f(\mathbf{x}) - f^* - \sum_{j=1}^{m} \sigma_j^*(\mathbf{x}) g_j(\mathbf{x}) = \sigma_0^*(\mathbf{x}) (\geq 0), \quad \forall \mathbf{x} \in \mathbb{R}^d;
\]

\[
(39) \quad \hat{L}(x^*) = 0.
\]
So in (38) the extended Lagrangian \( \hat{L} \) looks like the standard Lagrangian \( L \) in (36) except that the scalar weight \( \lambda_j^* \) is now replaced with the SOS polynomial weight \( \sigma_j^* \). Moreover, the scalar \( \hat{\lambda}_j = \sigma_j^*(x^*) \) is a standard Lagrange-KKT multiplier associated with the constraint \( g_j \geq 0 \) (like \( \lambda_j^* \) in (36)).

Interestingly, if the constraint \( g_j \geq 0 \) is not active at \( x^* \) (i.e., \( g_j(x^*) > 0 \)), then \( \hat{\lambda}_j = \sigma_j^*(x^*) = 0 \) but in general the SOS polynomial \( \sigma_j^* \) is not the trivial polynomial equal to zero. In fact, suppose that the constraint \( g_j \geq 0 \) is important even if it is not active at a global minimizer \( x^* \), meaning that if one removes that constraint in the definition (13) of \( S \), then the new global minimum of the modified problem \( P \) is strictly smaller than \( f^* \). Then quite remarkably, \( \sigma_j^* \neq 0 \). In other words, a non-trivial SOS multiplier \( \sigma_j^* \) in Putinar’s certificate of global optimality (34) identifies \( g_j \geq 0 \) as an important constraint, even if it is not active at global minimizers.

3.4. **Genericity.** In view of the remarkable form of Theorem 3.5, one may wonder how “generic” are the results of Theorem 3.5. It turns out that Theorem 3.5 holds generically in a rigorous sense. More precisely:

Let \( m \in \mathbb{N} \) and \( r_j \in \mathbb{N}, j = 0, \ldots, m \), be fixed, and consider the family of POPs whose (possibly empty) feasible set \( S \subset \mathbb{R}^d \) is as in (13) for some polynomials \( g_j \in \mathbb{R}[x]_{r_j} \), and its criterion is some polynomial \( f \in \mathbb{R}[x]_{r_0} \).

Recall that \( s(t) := \binom{d+\ell}{\ell} t^\ell \). So a vector \( \theta \in \mathbb{R}^a \) with \( a := \sum_{j=0}^m s(r_j) \) completely specifies an instance \( P(\theta) \) of such a problem \( P \). The next result is due to [96].

**Theorem 3.7.** There exists an integer \( L \) and finitely many real polynomials \( \varphi_1, \ldots, \varphi_L \in \mathbb{R}[\theta] \) in the coefficients \( \theta \) of the polynomials \( f, g_1, \ldots, g_m \), such that if \( \varphi_\ell(\theta) \neq 0 \) for all \( \ell = 1, \ldots, L \), then (32), strict complementarity and second-order sufficient KKT-optimality condition (33) hold at any global minimizer of problem \( P(\theta) \).

As a result, there exists \( n \in \mathbb{N} \) such that (34) and (35) hold at every global minimizer \( x^* \) of \( P(\theta) \), i.e., finite convergence of the Moment-SOS hierarchy is generic.

3.5. **The convex case.** In this section we consider the particular case when \( P \) is a convex program\(^5\), that is when the polynomials \( f \) and \(-g_j\) are all convex, and so the set \( S \) in (13) is convex. This class of problems is very important as they are considered “easy” or at least “easier” than non-convex problems. Indeed as any local optimum of \( P \) is a global optimum, then \( P \) can be solved by several powerful local optimization algorithms.

So as the Moment-SOS hierarchy is able to solve difficult non-convex problems \( P \), a natural question is: **How does the Moment-SOS hierarchy behaves when \( P \) is a convex program?**

The reason why such a question is relevant is because if the Moment-SOS hierarchy would not be efficient in solving a convex problem then one might raise reasonable doubts on its efficiency in solving even more difficult problems!

---

\(^5\)The set \( S \) in (13) may be convex even if the \(-g_j\)’s are not convex (e.g. they can be quasi-convex). **Convex programming** usually refers to the case where \( f \) and the \(-g_j\)’s are all convex.
SOS-convex programs. Let us first consider the class of SOS-convex polynomials.

**Definition 3.8.** A polynomial $f \in \mathbb{R}[x]$ is SOS-convex if its Hessian $\nabla^2 f$ is an SOS-matrix polynomial, that is, $\nabla^2 f = LL^T$ for some real matrix-polynomial $L \in \mathbb{R}[x]^{d \times s}$ (for some integer $s$). In particular, every SOS-convex polynomial is convex and all quadratic convex polynomials are SOS-convex.

One has the following characterizations of SOS-convexity.

**Theorem 3.9.** Let $f \in \mathbb{R}[x]$. The following four propositions are equivalent:

(i) $f$ is SOS-convex.

(ii) $\nabla^2 f$ is SOS.

(iii) $(x, y) \mapsto f(x)^2 + f(y)^2 - f((x + y)/2)$ is SOS.

(iv) $(x, y) \mapsto f(x) - f(y) - \langle \nabla f(y), (x - y) \rangle$ is SOS.

Notice that $f$ and $-g_j$ being convex, then necessarily their degree is either one or even. Importantly, SOS-convexity can be checked numerically by solving a semidefinite program (e.g. following Theorem 3.9(iii) and Section 2.2). The next result states that the Moment-SOS hierarchy somehow “recognizes” easy SOS-convex problems.

**Theorem 3.10.** Let $S$ be as in (13) and let Slater’s condition hold (i.e., the exists $x_0 \in S$ such that $g_j(x_0) > 0$ for all $j$). If $f$ and $-g_j$ are all SOS-convex then with $\nu_0 := \max \{ \deg(f)/2, \max_j [\deg(g_j)/2] \}$

\begin{equation}
    f - f^* = \sigma_0^* + \sum_{j=1}^m \lambda_j^* g_j
\end{equation}

for some scalars $\lambda_j^* \geq 0$ and some $\sigma_0^* \in \Sigma[x]_{\nu_0}$. In addition,

\begin{equation}
    f^* = \min_{\phi} \{ \phi(f) : \phi(1) = 1 \mid M_n(\phi) \geq 0, \phi(g_j) \geq 0, j = 1, \ldots, m \}.
\end{equation}

Moreover, $\phi^*(x_i) = x_i^*$, for all $i = 1, \ldots, d$, where $\phi^*$ is an optimal solution of (41), and $x^* \in S$ is a local (hence global) minimizer of $P$.

It is also rather straightforward to check that in (40), $\lambda^* = (\lambda_j^*)_{1 \leq j \leq m}$ are Lagrange-KKT multipliers at an optimal solution $x^* \in S$ of $P$.

Next, observe that the semidefinite Moment-relaxation (41) is a particular case of (26) where the constraints $M_{n-d_j}(g_j \cdot \phi) \geq 0$ are replaced with the simpler $M_0(g_j \cdot \phi) \geq 0$ (i.e. the scalar linear inequality constraint $\phi(g_j) \geq 0$).

However, if one does not know that $f$ and $-g_j$ are SOS-convex and one solves (26) as for a general POP, then one still obtains $f^* = \tau_{n_0}$, that is, the first Moment-relaxation of the hierarchy is exact. In other words, the Moment-SOS hierarchy has recognized that $P$ was a convex (easy) problem.

The reason why the Moment-relaxation (26) can be replaced with the simpler (41) is because linear functionals $\phi \in \mathbb{R}[x]_{\nu_0}$ such that $M_n(\phi) \geq 0$ have a nice property when acting on SOS-convex polynomials.
Lemma 3.11 (Jensen’s inequality for linear functionals). Let $\phi \in \mathbb{R}[x]_n^2$ be such that $M_n(\phi) \succeq 0$, $\phi(1) = 1$, and let $x^* := (\phi(x_1), \ldots, \phi(x_d)) \in \mathbb{R}^d$. Then

$$\phi(f) \geq f(x^*), \quad \text{for every SOS-convex polynomial } f \in \mathbb{R}[x]_{2n}. \quad (42)$$

So let $\phi^*$ be an optimal solution of

$$\tau'_n = \min_{\phi} \{ \phi(f) : \phi(1) = 1; M_n(\phi) \succeq 0; \phi(g_j) \geq 0, j = 1, \ldots, m \}.$$  

Of course $\tau'_n \leq f^*$, as $\tau'_n$ is the optimal value of a relaxation of $P$. As $f$ and $-g_j$ are SOS-convex, and with $x^* := (\phi^*(x_1), \ldots, \phi^*(x_d)) \in \mathbb{R}^d$,

$$\tau'_n = \phi^*(f) \succeq f(x^*); \quad 0 \leq \phi^*(g_j) \leq g_j(x^*), \quad j = 1, \ldots, m,$$

which implies $x^* \in S$ and $f(x^*) \leq \tau'_n \leq f^*$, so that $x^*$ is a global minimizer of $P$. General convex POPs. In the more general case of convex POP one also obtains finite convergence under some strict convexity assumption at every global minimizer $x^* \in S$.

Theorem 3.12. With $S \subset \mathbb{R}^d$ as in (13), assume that $Q(g)$ is Archimedean, Slater’s condition holds, and $f$ and $-g_j$ are convex, $j = 1, \ldots, m$. If $\nabla^2 f(x^*) > 0$ at every global minimizer $x^* \in S$ (assumed to be finitely many) then finite convergence takes place, that is, the Moment-relaxation (26) of $P$ is exact at some degree $n$. Moreover, the SOS-strengthening (24) of $P$ is also exact, and both (26) and (24) have an optimal solution $\phi^n$ and $(\lambda^*, \sigma^*_0, \ldots, \sigma^*_n)$, respectively.

So again without specifying that $P$ is convex, the Moment-SOS hierarchy will converge in finitely many steps. However in contrast to Theorem 3.9, in Theorem 3.12 one does not specify at which step $n$ finite convergence takes place.

3.6. General versus ad-hoc. One would like to emphasize that Theorem 3.5 is a quite general global-optimality condition that holds generically for POPs, hence with non-convex criterion and non-convex (and possibly disconnected) feasible sets $S$, and even with mixed-integer variables. The only requirement is to be able to translate all constraints of the problem into polynomial inequality and equality constraints.

Usually generality is at the price of reduced efficiency and usual algorithmic practice of optimization suggests to use ad-hoc algorithms, i.e., algorithms tailored to the type of problem one has to solve. Indeed for instance if $x_i \in \{0, 1\}, i \in I$, for some $I$, it is not a good idea to model this constraint with the equality constraints $x_i^2 - x_i = 0$, $i \in I$, and then use standard first-order or second-order methods to obtain a (only local) optimum. One typically uses branch & bound (or branch & cut) methods.

Remarkably, the Moment-SOS hierarchy does not suffer from its generality in just describing any POP by a set of polynomial inequality and equality constraints. (Of course some descriptions may be more interesting than others.) Indeed for instance, for SOS-convex programs and in particular convex quadratically constrained quadratic programs (convex QCQP), Theorem 3.9 ensures that finite convergence takes place at first step of the hierarchy, without the need of specifying that the
POP is SOS-convex. Similarly, if \( f \) and \( -g_j \) are all convex, and \( \nabla^2 f(x) > 0 \) at all global minimizers \( x \in S \), then finite convergence also takes place.

Of course again, we do not claim that the Moment-SOS hierarchy is the most efficient algorithm to solve such convex problems, and indeed other efficient algorithms exist. But this remark is to simply emphasize that somehow the Moment-SOS hierarchy recognizes easy problems (as one usually considers convex programs to be easier to solve) as finite convergence takes place quickly. On the other hand, the Moment-SOS hierarchy has also been recognized by the Theoretical Computer Science research community as a meta-algorithm which provides the best lower bounds for many combinatorial optimization problems, and in particular problems with \( \{0, 1\} \) (or \( \{-1, 1\} \)) variables like Maxcut and its variants, which are notoriously difficult NP-hard problems. It is now considered as an important tool for proving/disproving the celebrated Khot’s Unique Games conjecture.

3.7. Rates of convergence. In this section one provides rates of convergence for the Moment-SOS hierarchy of lower bounds on general compact basic semi-algebraic sets. Those rates have been refined for specific sets like the unit sphere \( \mathbb{S}^{d-1} \), the unit ball \( \mathbb{B}^d = \{ x \in \mathbb{R}^d : \|x\|^2 \leq 1 \} \), the box \( [-1, 1]^d \), and the simplex \( \Delta^d = \{ x \in \mathbb{R}^d : 1 - e^T x \geq 0 \} \).

Table 3.7 below is taken from [125]. The first column is related to the set \( S \subset \mathbb{R}^d \) and “Archimedean” means that the quadratic module \( Q(g) \) in (11) associated with \( S \), is Archimedean (an algebraic certificate of its compactness used in Putinar’s Positivstellensatz). The third column “Certificate” specifies if in the Moment-SOS hierarchy one uses Putinar’s certificate (Theorem 2.2) or the more costly Schmüdgen’s certificate (Theorem 2.3) for the semidefinite relaxation (24). In the notation \( O(1/n^c) \), \( n \) is the order (or degree) of the semidefinite relaxations (24)-(26), and \( c \) is some positive constant. The rate \( O(1/n^c) \) means that \( f^* - \tau_n \leq M/n^c \) for some constant \( M > 0 \), where \( f^* \) is the global minimum and \( \tau_n (\leq f^*) \) is as in (26).

Finally, for optimization of trigonometric polynomials (and so for POPs on the box \([0, 1]^d \) as well) and under some condition on global minimizers (isolated and with positive definite Hessian), an exponential rate of convergence has been provided in [6]. This shows that beyond general results like those in Table 3.7, there is hope for even faster rates convergence, at the price of some additional conditions on the minimizers and/or the set \( S \).

3.8. Handling sparsity. As already mentioned, in its canonical form (24)-(26), the Moment-SOS hierarchy is limited to problems $P$ of modest dimension, even though for fixed dimension $d$ the size-parameters of each moment-relaxation (26) are polynomial in the degree $n$. This is because (26) being a semidefinite program, efficient algorithms based on interior-point methods are still very time-consuming. Fortunately, practice reveals that moment-relaxations (26) of low degree $n$ already provide tight lower bounds on $f^*$, and are sometimes exact. In addition, large-scale problems $P$ usually exhibit some sparsity pattern and/or symmetries. For instance, as is typically for applications in large dimension $d$, (i) each constraint $g_j \geq 0$ in (13) sees only some small subset of variables $\{x_i : i \in I_k\}$ with $I_k \subset \{1, \ldots, d\}$, and (ii) the criterion $f$ of $P$ is very often a sum $\sum_k f_k$ of (low degree) polynomials $f_k$, where each polynomial $f_k$ only sees variables $\{x_i : i \in I_k\}$. This type of sparsity is called correlative-sparsity. Also another type of sparsity called term-sparsity occurs when all polynomials $f$ and $g_j$ in the description (13) of $P$ contains a few monomials only. It turns out that correlative- and term-sparsity can be exploited so as to yield a new sparsity-adapted Moment-SOS hierarchy of semidefinite relaxations of $P$. These two types of sparsity can even be combined for further efficiency; see e.g. [138] and [78].

For sake of completeness, one next briefly describes how correlative sparsity allows to define an appropriate sparsity-adapted Moment-SOS hierarchy that can handle large-scale POP.

Assumption 3.13. With $P$ as in (1) with $S \subset \mathbb{R}^d$ as in (13):

- $I_0 := \{1, \ldots, d\} = \bigcup_{k=1}^{p} I_k$ (with possible overlaps)
- $\mathbb{R}[x; I_k]$ is the ring of polynomials in the variables $\{x_i : i \in I_k\}$.
- $f = \sum_{k=1}^{p} f_k$ with $f_k \in \mathbb{R}[x; I_k]$, $k = 1, \ldots, p$. 
- For each $j = 1, \ldots, m$, $g_j \in \mathbb{R}[x; I_k]$ for some $k \in \{1, \ldots, p\}$, and so let $J_k := \{j : g_j \in \mathbb{R}[x; I_k]\}$, $k = 1, \ldots, p$.

Of course, as one next sees, Assumption 3.13 is interesting when the cardinal $\#I_k$ of $I_k$ is small for every $k = 1, \ldots, p$.

Observe that if $g \in \mathbb{R}[x; I_k]$ then in the expansion $g(x) = \sum_{\alpha} g_{\alpha} x^\alpha$, $\alpha_i = 0$ if $i \notin I_k$, whenever $g_{\alpha} \neq 0$. So let

$$\mathcal{N}^{(k)} := \{\alpha \in \mathbb{N}^d : \alpha_i = 0, \forall i \notin I_k\}, \quad k = 1, \ldots, p;$$

$$\mathcal{N}^{(k)}_n := \{\alpha \in \mathbb{N}^{(k)} : \sum_i \alpha_i \leq n\}, \quad k = 1, \ldots, p.$$

Next, given $\phi = (\phi_{\alpha})_{\alpha \in \mathbb{N}^d}$, define $M_n(\phi; I_k)$ to be the submatrix of $M_n(\phi)$ whose rows and columns are associated with monomials $(x^\alpha)$, $\alpha \in \mathcal{N}^{(k)}_n$. Similarly, when $j \in J_k$, the localizing matrix $M_n(g_j \cdot \phi; I_k)$ is the submatrix of $M_n(g_j \cdot \phi)$ whose rows and columns are associated with monomials $(x^\alpha)$, $\alpha \in \mathcal{N}^{(k)}_{n-d_j}$.
When Assumption 3.13 holds, it is quite natural to define moment-relaxations

\[
\tau_n^{\text{sparse}} = \inf_{\phi = (\phi_i)} \left\{ \sum_{k=1}^{p} \phi(f_k) : \phi_0 = 1 ; \right. \\
\left. M_n(\phi; I_k) \geq 0, \quad k = 1, \ldots, p ; \right. \\
M_{n-d_j}(g_j \cdot \phi; I_k) \geq 0, \quad \forall j \in J_k ; \quad k = 1, \ldots, p \} .
\]

(43)

The reason why (43) is appealing is because the size of the matrix \( M_n(\phi; I_k) \) is \( s_k(n) := \binom{n+d}{d} \) while that of \( M_{n-d_j}(g_j \cdot \phi) \) is \( s(n-d_j) \). Therefore if \( \#I_k \ll d \), then \( s_k(n) \ll s(n) \) and \( s_k(n-d_j) \ll s(n-d_j) \). So for a semidefinite solver it is always definitely better to have several (and even possibly a lot) of small size matrices rather than a single large size matrix constrained to be psd.

It is quite straightforward to obtain that \( \tau_n^{\text{sparse}} \leq f^* \) for all \( n \geq n_0 \). Indeed \( \tau_n^{\text{sparse}} \leq \tau_n \leq f^* \) (with \( \tau_n \) being the optimal value of the degree-\( n \) moment relaxation (26)). Moreover the sequence \( (\tau_n^{\text{sparse}})_{n \geq n_0} \) is monotone non decreasing and being bounded above, converges to some \( \gamma \leq f^* \).

Again assume (possibly after scaling) that the quadratic polynomial \( 1 - \|x\|^2 \) is in the quadratic module \( Q_1(g) \), and therefore one may and will add the \( p \) redundant constraints

\[
1 - \sum_{i \in I_k} x_i^2 \geq 0, \quad k = 1, \ldots, p ,
\]

in the definition of \( S \).

**Theorem 3.14 ([58]).** Let \( S \subset \mathbb{R}^d \) be as in (13) with constraints (44) in its definition (13), and consider the hierarchy of semidefinite relaxations (43) with optimal value \( \tau_n^{\text{sparse}} \). Then \( \tau_n^{\text{sparse}} \uparrow \gamma \leq f^* \), as \( n \) increases. Moreover, if for every \( k = 2, \ldots, p , \)

\[
I_k \cap \left( \bigcup_{j=1}^{k-1} I_j \right) \subseteq I_\ell ,
\]

(45)

for some \( \ell \in \{1, \ldots, k-1\} \), then \( \gamma = f^* \).

The condition (45) is called the Running Intersection Property. It has the following important property: Suppose that we are given \( p \) probability measures \( \phi_j \) on \( \mathbb{R}^{\#I_j} \), \( j = 1, \ldots, p \), which are compatible, i.e., such that for all pairs \((i, j)\) with \( I_i \cap I_j \neq \emptyset \),

\[
\int x^\alpha \, d\phi_i(x \in I_i \cap I_j) = \int x^\alpha \, d\phi_j(x \in I_i \cap I_j) , \quad \forall \alpha \in \mathbb{N}^{\#I_i \cap I_j} .
\]

If (45) holds then there exists a probability measure \( \phi \) on \( \mathbb{R}^d \) such that

\[
\int x^\alpha \, d\phi = \int x^\alpha \, d\phi_j , \quad \forall \alpha \in \mathbb{N}^{\#I_j} , \quad j = 1, \ldots, p .
\]

That is, from local measures \( \phi_j \) on \( \mathbb{R}^{\#I_j} \) which are compatible, one may reconstruct a global measure on \( \mathbb{R}^d \) whose marginal on \( \mathbb{R}^{\#I_j} \) is \( \phi_j \), for all \( j = 1, \ldots, p \). Therefore the local information provided by the \( \phi_j \)’s corresponds to a partial (but consistent) knowledge of a global information that we do not necessarily need to know.
On the dual side of positive polynomials we have the following sparse version of Putinar’s Positivstellensatz.

**Theorem 3.15** (Sparse Positivstellensatz [58]). Let $S \subset \mathbb{R}^d$ be as in (13) with constraints (44) in its definition (13) and let $f = \sum_{k=1}^{p} f_k$ with $f_k \in \mathbb{R}[x; I_k]$, $k = 1, \ldots, p$. If (45) holds and $f > 0$ on $S$ then

$$
(46) \quad f(x) = \sum_{k=1}^{p} \left( \sigma_{0,k}(x) + \sum_{j \in J_k} \sigma_{j,k}(x) g_j(x) \right), \quad \forall x \in \mathbb{R}^d,
$$

for some SOS polynomials $\sigma_{0,k}, \sigma_{j,k} \in \Sigma[x, I_k]$, $j \in J_k$, $k = 1, \ldots, p$.

Theorem 3.15 provides a sparsity-adapted certificate of positivity à la Putinar where the SOS weight $\sigma_j$ associated with a constraint $g_j \geq 0$, $j \in J_k$, “sees” only the variables $\{x_i : i \in I_k\}$.

To cite a few examples, such sparsity-adapted semidefinite relaxations have been implemented for solving the Optimal Power Flow (OPF) problem in management of large-scale electricity networks [89, 88], in geometric perception [141], Robotics [115], sensor network localization [94], as well as in [99].

### 3.9. Notes and sources

Section 3 is mainly based on [60, 63] where the reader can find all proofs (or references to papers with proofs).

Section 3.1. The Moment-SOS hierarchy was first proposed in [54, 55].

Section 3.3-Section 3.4 Theorem 3.5 and Theorem 3.7 are due to [96]. In [95] the author also shows that the Flatness condition (29) at an optimal solution of the Moment-relaxation (26), also holds generically. A refinement of these results is provided in [10]. Those results are important as they guarantee that the Moment-SOS hierarchy as finite convergence, generically (in the sense of Theorem 3.7), and that one may extract global minimizers from an optimal solution of the semidefinite relaxation (26).

Section 3.5 and 3.6 are mainly taken from [63, Chapter 13]. See also [59, 43].

Section 3.7 is essentially based on [125].

Section 3.8. Correlative-sparsity was first proposed as a heuristic in [45, 135] while its proof of convergence was provided in [58]. Term-sparsity was initially described in [136] and further exploited in the TSSOS hierarchy in [137]. Finally, the combination of correlative- and term-sparsity which yields the CS-TSSOS hierarchy is described in [138]. The interested reader is referred to the book [78] which, among other things, describes various forms of sparsity and associated Moment-relaxations based on appropriate cones of positive polynomials.

Finally let us mention that a lower bound $\tau_n \leq f^*$, obtained by the Moment-SOS hierarchy even at low degree $n$, can also be useful to “gauge” how far from $f^*$ is the value $f(\hat{x})$ of a feasible solution $\hat{x} \in S$ obtained by some numerical (local) optimization algorithm. Indeed if $f(\hat{x}) - \tau_n$ is not too large, then somehow $\tau_n$ certifies that the local optimization algorithm has produced a good feasible solution.
4. The Moment-LP hierarchy

As seen in Section 3, the Moment-SOS hierarchy is based on the use of Putinar’s certificate of positivity (15) and its convergence relies on Theorem 2.2. One next provides a hierarchy of LP-relaxations whose associated sequence of optimal values also converges to the global optimum from below. Similarly as for the Moment-SOS hierarchy, the Moment-LP hierarchy is also based on a positivity certificate, namely that in (19), and its convergence relies on Theorem 2.5.

Assumption 4.1. With \( S \subset \mathbb{R}^d \) as in (13), assume that \( S \) is compact, \( 0 \leq g_j \leq 1 \) on \( S \), for every \( j = 1, \ldots, m \), and the polynomials \( \{1, g_1, \ldots, g_m\} \) generate \( \mathbb{R}[x] \).

As \( S \) is compact one may always re-scale the \( g_j \)’s (and possibly add redundant constraints) to make the new definition of \( S \) satisfy Assumption 4.1. For more details the interested reader is referred to [60].

Next, with same notation \( g \) and \( 1 - g \) as in (19), and \( n \in \mathbb{N} \), introduce the following linear program (LP):

\[
(47) \quad \rho_n = \min_{\phi} \{ \phi(f) : \phi(1) = 1 ; \phi(g^\alpha (1 - g)^\beta) \geq 0, \ (\alpha, \beta) \in \mathbb{N}_n^{2m} \},
\]

where \( \phi = (\phi\gamma)_{\gamma \in \mathbb{N}_n^d} \) with \( s_n := \max_{(\alpha, \beta) \in \mathbb{N}_n^{2m}} \deg(g^\alpha (1 - g)^\beta) \).

By its very nature, (47) is a linear program and is a relaxation of \( P \) because the constraints in (47) are only necessary conditions on \( \phi \) to be moments of a probability measure supported on \( S \); see Theorem 2.5. The dual of (47) is the linear program

\[
(48) \quad \rho_n^* = \max_{c_{\alpha\beta} \geq 0, \lambda} \{ \lambda : f - \lambda = \sum_{(\alpha, \beta) \in \mathbb{N}_n^{2m}} c_{\alpha\beta} g^\alpha (1 - g)^\beta \}.
\]

In similar manner as (24) was a SOS-strengthening of \( P \) in (3), the LP (48) is now an LP-strengthening of \( P \) in (3). Of course, from duality for linear programs, \( \rho_n = \rho_n^* \) for all \( n \).

Example 4.2. To better visualize how the LP (47) looks like, consider the toy example where \( S = [0, 1] = \{ x : x \geq 0 ; (1 - x) \geq 0 \} \subset \mathbb{R} \). Then for \( n = 2 \), \( \phi = (\phi_j)_{0 \leq j \leq 2} \), and

\[
\phi(1) = \phi_0 ; \phi(x) = \phi_1 ; \phi(1 - x) = \phi_0 - \phi_1 ; \phi(x^2) = \phi_2
\]

so that with \( f \in \mathbb{R}[x]_2 \), \( x \mapsto f(x) = \sum_{k=0}^2 f_k x^k \),

\[
\rho_2 = \min_{\phi} \{ \sum_{k=0}^2 \phi_k f_k : \phi_0 = 1 ; \phi_1 \geq 0 ; \phi_0 - \phi_1 \geq 0 ; \phi_1 - \phi_2 \geq 0 ; \phi_0 - 2\phi_1 + \phi_2 \geq 0 \}. \]

Similarly,

\[
\rho_2^* = \max_{c_{\alpha\beta} \geq 0, \lambda} \{ \lambda : f(x) - \lambda = c_{00} + c_{10} x + c_{01} (1 - x) + c_{20} x^2 + c_{11} x(1 - x) + c_{02} (1 - x)^2, \ \forall x \in \mathbb{R} \}, \]

or equivalently,

\[
\rho_2^* = \max_{c \geq 0, \lambda} \ \{ \lambda : \ f_0 - \lambda = c_0 + c_1 ; \ f_1 = c_1 - c_0 + c_1 + c_2 ; \ f_2 = c_2 - c_1 + c_2 \}.
\]

Equality constraints are treated as for the Moment-SOS hierarchy. For instance, in (47), a boolean constraint \(x_i^2 = x_i\) of \(P\), translates into the moment equality constraints \(\phi(x_i^k) = \phi(x_i)\) for all \(k \leq n\).

**Theorem 4.3 ([60]).** With \(S\) as in (13), let Assumption 4.1 hold. Then as \(n\) increases, the sequences \((\rho_n)_{n \in \mathbb{N}}\) and \((\rho_n^*)_{n \in \mathbb{N}}\) are monotone non-decreasing and converge to the global minimum \(f^*\) of \(P\).

### 4.1. The case of a convex polytope.

We now assume that \(S \subseteq \mathbb{R}^d\) is a convex polytope (with nonempty interior), i.e., for each \(j = 1, \ldots, m\), \(g_j \in \mathbb{R}[x]_1\) (\(g_j\) is a polynomial of degree 1). In this case Theorem 2.5 specializes.

**Theorem 4.4 ([34]).** Let \(S \subseteq \mathbb{R}^d\) be as in (13) with nonempty interior and with all \(g_j\) of degree 1, and assume that \(S\) is compact (hence \(S\) is a convex polytope). If \(f \in \mathbb{R}[x]\) is positive on \(S\) then there exists \(n \in \mathbb{N}\) and a nonnegative vector \(c = (c_\alpha)_{\alpha \in \mathbb{N}^m}\), such that:

\[
f = \sum_{\alpha \in \mathbb{N}^m} c_\alpha g_\alpha^*.
\]

So the obvious analogue of (47) for a convex polytope now reads:

\[
\rho_n = \min_{\phi} \{ \phi(f) :\ \phi(1) = 1 ; \ \phi(g_\alpha^*) \geq 0, \ \alpha \in \mathbb{N}^m \}
\]

where \(\phi = (\phi_\gamma)_{\gamma \in \mathbb{N}^m}\) with \(s_n := \max_{\alpha \in \mathbb{N}^m} \deg(g_\alpha^*)\). The dual of (50) reads:

\[
\rho_n^* = \max_{\alpha \geq 0, \lambda} \{ \lambda : f - \lambda = \sum_{\alpha \in \mathbb{N}^m} c_\alpha g_\alpha^* \}.
\]

So an analogue of Theorem 4.3 reads:

**Theorem 4.5.** Let \(S \subseteq \mathbb{R}^d\) be as in (13) with nonempty interior and with all \(g_j\) of degree 1, and assume that \(S\) is compact (hence \(S\) is a convex polytope). Let \(\rho_n\) (resp. \(\rho_n^*\)) be as in (50) (resp. (51)). Then as \(n\) increases, both sequences \((\rho_n)_{n \in \mathbb{N}}\) and \((\rho_n^*)_{n \in \mathbb{N}}\) are monotone non-decreasing and converge to the global minimum \(f^*\) of \(P\).

On 0/1 discrete problems and RLT. Consider discrete optimization problems \(P\) \(\min \{ f(x) : x \in S \}\) for which the set of feasible solutions is of the form:

\[
S = \{ x \in \{0, 1\}^d : g_j(x) \geq 0, \ j = 1, \ldots, m \} = \{ x \in \mathbb{R}^d : g_j(x) \geq 0, \ j = 1, \ldots, m ; x_i^2 - x_i = 0, \ i = 1, \ldots, d \}.
\]

This formulation includes many combinatorial optimization problems, including the celebrated MAXCUT problems and its variants on \(\{-1, 1\}^d\) (after a simple linear transformation). The so-called RLT [121, 122] is a reformation-linearization technique (already proposed in the nineties) to solve \(P\) when \(f\) and the \(g_j\)’s are all.
linear. In RLT one “lifts” $P$ in a space of higher dimension: Namely, with $t \leq d$ fixed:

- One defines order-$t$ bound-factors constraints

$$A_{J_1, J_2}(x) := \prod_{i \in J_1} x_i \prod_{j \in J_2} (1 - x_j) \geq 0, \quad \forall (J_1, J_2),$$

where $J_1, J_2 \subseteq \{1, \ldots, d\}$, $J_1 \cap J_2 = \emptyset$ and $|J_1 \cup J_2| = t$, and

- For every $j = 1, \ldots, m$, the additional constraint factor-based restrictions

$$A_{J_1, J_2} g_j(x) \geq 0, \quad \forall (J_1, J_2).$$

Then in each such constraints, one replaces every occurrence of the power $x_i^k$ with $x_i$, and one “linearizes” the resulting polynomial constraint, i.e., every occurrence of the non-linear monomial $\prod_{i \in J} x_i$ is replaced with a variable $y_J$ constrained to be nonnegative.

One ends up with a linear program in a space of higher dimension $s(t + 1)$ which is an LP-approximation of $P$. In the RLT construction of this LP-relaxation (which ignores constraints of the form $g^a \geq 0$), one recognizes a particular case of the Moment-LP relaxation (47) of $P$ in the presence of boolean constraints $x_i^2 = x_i$, for all $i = 1, \ldots, d$. So it is fair to say that RLT, the first systematic construction of a “hierarchy” of LP-relaxations for 0/1 programs, was implicitly based on positivity certificates of the flavor (19), i.e., à la Krivine-Vasilescu.

4.2. **Contrasting the Moment-SOS hierarchy with the Moment-LP hierarchy.**

At first glance one is tempted to favor the Moment-LP hierarchy because state-of-the-art LP solvers are very efficient and can solve potentially very large (even huge) scale LPs, whereas in its canonical form (26)-(24) the Moment-SOS hierarchy is limited to POPs of modest dimension and small degree of relaxation $n$, unless some sparsity and/or symmetries can be exploited. Unfortunately the Moment-LP hierarchy has some serious drawbacks that also limit its application to problems of modest dimension. Indeed, except for discrete and linear POPs, finite convergence is impossible in general, even for convex problems!

However, for discrete problems with 0/1 variables, the Moment-LP hierarchy can be combined with ad-hoc heuristics. For instance one may try to solve such 0/1 problems with Branch & Bound methods where at each node of the search-tree, a lower bound associated with the node is computed by solving an appropriate Moment-LP relaxation of the discrete subproblem associated with the node in the Branch & Bound strategy. Finite convergence is not possible in general. For clarity and simplicity of exposition, we illustrate this claim in the case where $S$ is a convex polytope.

**Proposition 4.6.** Let $S \subset \mathbb{R}^d$ be a convex polytope and consider the LP-strengthening (51) of $P$. If $P$ has finitely many global minimizers and (51) is exact for some degree $n$, then necessarily every global minimizer $x^*$ is a vertex of $S$. 
Proof. Let $0 \leq c^* \neq 0$ be an optimal solution of the degree-$n$ LP-relaxation (51), and assume that (51) is exact, i.e., $\rho_n^* = f^*$. Then

$$f(x) - f^* = \sum_{a \in \mathbb{Z}^m_n} c_a^* g_1(x)^{a_1} \cdots g_m(x)^{a_m}, \quad \forall x \in \mathbb{R}^d.$$  

In particular, at every global minimizer $x^* \in S$,

$$0 = f(x^*) - f^* = \sum_{a \in \mathbb{Z}^m_n} c_a^* g_1(x^*)^{a_1} \cdots g_m(x^*)^{a_m}, \quad \forall x \in \mathbb{R}^d.$$  

So assume that there exists a global minimizer $x^* \in S$ which is not a vertex, and let $I(x^*) := \{ j \in \{1, \ldots, m\} : g_j(x^*) = 0 \}$ be the set of active constraints at $x^* \in S$. Observe that $I(x^*) \neq \emptyset$ because otherwise we would have $g_j(x^*) > 0$ for all $j = 1, \ldots, m$, which in turn by (53) implies $c^* = 0$, in contradiction with $c^* \neq 0$. So (53) already rules out the possibility of having a global minimizer in int($S$). Next, from (53) one may infer

$$c_a^* > 0 \quad \Rightarrow \quad \alpha_j > 0 \text{ for some } j \in I(x^*).$$  

As $x^*$ is not a vertex and $P$ has only finitely many global minimizers, the set $\{ y \in S : I(y) = I(x^*) \}$ contains a point $\hat{y} \in S$ which is not a global minimizer, i.e., $f(\hat{y}) > f^*$. But then (52) combined with (54) yields the contradiction

$$0 = \sum_{a \in \mathbb{Z}^m_n} c_a^* g_1(\hat{y})^{a_1} \cdots g_m(\hat{y})^{a_m} = f(y) - f^* > 0.$$  

So Proposition 4.6 implies that for all problems $P$ (on convex polytopes) with finitely many minimizers, a necessary condition for some degree-$n$ LP-strengthening (51) to be exact is that every global minimizer is a vertex of $S$. In particular this condition rules out most convex POPs on a polytope, with a nonlinear criterion $f$ as in general a local (hence global) minimizer is not a vertex of $S$. (However, if $f$ is linear, i.e., if $P$ is a linear program, then (51) is exact with $n = 1$.)

A similar conclusion is also valid for POPs on even more general basic semi-algebraic sets $S$ and the LP-strengthening (48). Indeed, as in Proposition 4.6 and for same reasons, if such a POP has finitely many minimizers, then a necessary condition for (48) to be exact at some degree $n$, is that for every global minimizer $x^* \in S$, the set $\{ y \in S : I(y) = I(x^*) \}$ contains only global minimizers of $P$. Such a condition is very restrictive and rules out most problems $P$, in particular convex problems!

4.3. Notes and sources. Section 4 is mainly taken from [57, 63, Chapter 9]. In [75] the Moment-SOS hierarchy for 0/1 variables is described with specific notation proper to Graph theory and is embedded in the family of lift-and-project hierarchies, with among them the Lovasz-Schrijver and Sherali-Adams hierarchies. In particular the author shows that the Moment-SOS dominates the other lift-and-project hierarchies.

If LP-hierarchies are not efficient when used alone to solve optimization problems, they still can be useful when associated with other techniques of discrete
optimization; for instance as in [2] when used in conjunction with Branch-and-Bound.

5. A Moment-SOS hierarchy of upper bounds

In this section one considers another (less known) Moment-SOS hierarchy which provides a monotone non-increasing sequence \((\kappa_n)_{n \in \mathbb{N}}\) of upper bounds on the global minimum \(f^*\) of \(P\) defined in (3). For each “degree” \(n\), the upper bound \(\kappa_n \geq f^*\) is now computed by solving a very specific semidefinite program as it has only a single variable. In fact its dual reduces to computing the smallest generalized eigenvalue of a pair of moment-matrices.

5.1. A first multivariate formulation. Consider problem \(P\) in (3) with feasible set \(S \subset \mathbb{R}^d\) as in (13), and let \(\mu\) be a Borel (reference) measure on \(S\) with \(\text{supp}(\mu) = S\).

Assumption 5.1. (i) the set \(S \subset \mathbb{R}^d\) is compact with nonempty interior.
(ii) The vector of moments \(\mu = (\mu_\sigma)_{\sigma \in \Sigma^d}\) is available in closed form, or can be computed efficiently.

Of course in view of Assumption 5.1(ii), the set \(S\) has to be rather specific and indeed typical such sets are the unit box \([-1, 1]^d\), the Euclidean unit ball \(B(0, 1) = \{x : \|x\| \leq 1\}\), the canonical simplex \(\Delta^d = \{x \in \mathbb{R}^d : e^T x \leq 1\}\), the discrete hypercube \([-1, 1]^d\), and their image by an affine transformation. Even though such sets \(S\) are rather specific, the associated problems \(P\) cover many interesting NP-hard optimization problems.

Theorem 5.2. Let Assumption 5.1 hold, and with \(n \in \mathbb{N}\) fixed, consider the semidefinite problems:

\[
\kappa_n = \inf_{\sigma \in \Sigma^d} \left\{ \int f \sigma \, d\mu : \int \sigma \, d\mu = 1 \right\}, \quad n \in \mathbb{N};
\]

\[
\kappa_n^* = \sup_{\lambda} \{ \lambda : \lambda M_n(\mu) \preceq M_n(f \cdot \mu) \}, \quad n \in \mathbb{N}.
\]

Then:

\[
\kappa_n = \kappa_n^*; \quad f^* \leq \kappa_{n+1} \leq \kappa_n, \ \forall n \in \mathbb{N}; \quad \lim_{n \to \infty} \kappa_n = f^*.
\]

Crucial in the proof of convergence, which can be found in [61, Theorem 4.2], is the Nichtnegativstellensatz Theorem 2.4. It turns out that (56) is just computing the smallest generalized eigenvalue associated with the pair of symmetric matrices \((M_n(f \cdot \mu), M_n(\mu))\) for which specialized softwares exist. If both matrices are expressed in a polynomial basis of \(\mathbb{R}[x]_n\) formed by polynomials that are orthonormal with respect to \(\mu\) then \(M_n(\mu)\) becomes the identity matrix \(I\), and \(\tau_n^*\) is just the smallest eigenvalue of \(M_n(f \cdot \mu)\).

Computational consideration. Filling up entries of both matrices \(M_n(\mu)\) and \(M_n(f \cdot \mu)\) is straightforward. So the main effort is about computing the generalized eigenvalue of the couple of (symmetric) matrices \((M_n(f \cdot \mu), M_n(\mu))\) which can be done via standard softwares for eigenvalue computation. However, and even if they are symmetric, computing \(\kappa_n\) is quite challenging because of the size \(O(n^d)\) of the involved matrices as \(n\) increases.
Remark 5.3. A refinement of (55) is to consider polynomial densities \( \sigma \) nonnegative on \( S \) (instead of SOS). That is, replace (55) with

\[
\hat{\kappa}_n = \inf_{\sigma \in Q_n(g)} \{ \int f \sigma \, d\mu : \int \sigma \, d\mu = 1 \}, \quad n \in \mathbb{N},
\]

where \( Q_n(g) \) is the degree-2\( n \) truncated quadratic module associated with the generators \( g \) that define \( S \); see (12). For instance with \( S \) being the unit box,

\[
Q_n(g) = \{ \sigma_0 + \sum_{j=1}^d \sigma_j (1 - x_j^2) ; \sigma_0 \in \Sigma[x]_n ; \sigma_j \in \Sigma[x]_{n-1}, \ j = 1, \ldots, m \}.
\]

Of course \( f^* \leq \hat{\kappa}_n \leq \kappa_n \) for all \( n \) and therefore, in view of Theorem 5.2, \( \hat{\kappa}_n \downarrow f^* \) as \( n \) increases.

5.2. An alternative univariate formulation. Let the (univariate) Borel measure \( \#\mu \) be the pushforward of \( \mu \) on \( \mathbb{R} \) by the mapping \( f \), that is:

\[
\#\mu(B) = \mu(f^{-1}(B)), \quad \forall B \in \mathcal{B}(\mathbb{R}),
\]

where \( \mathcal{B}(\mathbb{R}) \) is the usual Borel \( \sigma \)-algebra generated by the open sets of \( \mathbb{R} \). By construction of \( \#\mu \), \( \text{supp}(\#\mu) = f(S) \), and therefore:

\[
f^* = \min_{\hat{\epsilon}} \{ z : z \in \text{supp}(\#\mu) \}.
\]

Moreover the moments \( (\#\mu_j)_{j \in \mathbb{N}} \) of \( \#\mu \) satisfy:

\[
\#\mu_j = \int_{f(S)} z^j d\#\mu(z) = \int_S f(x)^j d\mu(x), \quad \forall j \in \mathbb{N}.
\]

As all moments \( \mu_0 \) of \( \mu \) are available, the \( \#\mu_j \)'s can be obtained exactly, for instance, by expanding the polynomial \( f^j \) in the canonical basis \( (x^a) \),

\[
x \mapsto f(x)^j = \sum_{a \in \mathbb{N}^d} \theta_{a}^{(j)} x^a; \quad \#\mu_j = \sum_{a} \theta_{a}^{(j)} \mu_a.
\]

However, notice that even though the above expansion is always possible, it can become very tedious if \( j \) is large, even for modest dimension \( d \).

Theorem 5.4. Let \( \#\mu \) be the measure on \( \mathbb{R} \) in (59) (the pushforward of \( \mu \) by \( f \)), and let

\[
\rho_n := \inf_{\sigma \in \Sigma[z]_n} \{ \int z^j \sigma \, d\#\mu : \int \sigma \, d\#\mu = 1 \}, \quad n \in \mathbb{N};
\]

\[
\rho_n^* := \sup_{\lambda} \{ \lambda : \lambda M_n(\#\mu) \leq M_n(z \cdot \#\mu) \}, \quad n \in \mathbb{N}.
\]

Then \( (\rho_n)_{n \in \mathbb{N}} \) is a monotone non increasing sequence such that \( \rho_n \downarrow f^* \) as \( n \) increases. In addition, and letting \( d_f = \deg(f) \), one obtains \( \rho_n \geq \kappa_{nd_f} \) for every \( n \in \mathbb{N} \) (where \( \kappa_f \) is defined in (55)) because if \( \sigma \in \Sigma[z]_n \) is a feasible solution of (62) then \( \sigma \circ f \in \Sigma[x]_{nd_f} \) is a feasible solution of (55) with same value.
A detailed proof can be found in [65]. There is a striking difference between the hierarchies of upper bounds \((\kappa_n)_{n \in \mathbb{N}}\) in (55) and \((\rho_n)_{n \in \mathbb{N}}\) in (62). The latter involves univariate moment and localizing matrices. Both matrices are Hankel matrices of size \(O(n)\) (in contrast to multivariate Hankel-type matrices of size \(O(n^d)\) for computing \(\kappa_n\)). Therefore computing the generalized eigenvalue \(\rho_n\) is much easier than computing \(\kappa_n\).

On the other hand, filling up all entries of the Hankel moment matrix \(M_n(\#\mu)\) is in principle easy but tedious. Indeed if \(f^j\) is expanded in the monomial basis then its integration (61) w.r.t. \(\mu\) is straightforward. However as already noted, such an expansion can be quite costly if \(j\) is not small (even for modest dimension \(d\)).

Rates of convergence. It is worth noticing that similarly as for the hierarchy of lower bounds, \(O(1/n^2)\) rates of convergence have also been obtained for the hierarchy of upper bounds (55)-(56) on the sets \(S_1, B(0,1), [-1,1]^d, \text{ and } \Delta^d\); see [125, Table 2, p. 2615].

5.3. Notes and Sources. Section 5 is essentially based on [61] and [62]; the univariate formulation is from [65]. In a series of papers, de Klerk, Laurent and collaborators have obtained rates of convergence \(\kappa_n \downarrow f^*\) (multivariate) and \(\rho_n \downarrow f^*\) (univariate) as \(n\) grows, by playing with various reference measures \(\mu\) on \(S\) and a clever choice of appropriate families of densities. The approach is also interesting in its own right as it is a mix of various and sophisticated techniques, including polynomial kernels and asymptotics for roots of some distinguished orthogonal polynomials. Moreover it turns out that such techniques have been also useful to obtain rates of convergence for the Moment-SOS hierarchy of lower bounds on specific sets \(S\); for more details the interested reader is referred to [125] and references therein.

6. Some applications of the Moment-SOS hierarchy

In this section one briefly describes how the Moment-SOS hierarchy can be applied to help solve several problems in various fields of Science and Engineering. In brief, problems where the Moment-SOS hierarchy is a relevant tool, are problems which have an equivalent formulation as an instance of the the so-called Generalized Moment Problem (GMP in short) whose description is only through polynomials and semi-algebraic sets (i.e., GMP with algebraic data). Indeed the list of potential applications of the GMP is almost endless, with polynomial optimization being its simplest instance.

As is to be expected from what one has seen for optimization, the GMP can be formulated in a primal form (via moments) or a dual form (via polynomials). Its primal form is an infinite-dimensional and linear (hence convex) optimization problem on measure spaces, which reads:

\[
\text{GMP} : \inf_{\phi_1, \ldots, \phi_s} \left\{ \sum_{j=1}^s \int f_j \, d\phi_j \quad \text{s.t.} \quad \sum_{j=1}^s \int h_{kj} \, d\phi_j \geq b_k, \quad k \in \Gamma; \right. \\
\left. \text{supp}(\phi_j) \subset S_j, \quad j = 1, \ldots, s \right\},
\]
where all functions \( f_j, h_k \) are polynomials, \( \phi_j \) are Borel measures whose supports \( S_j \subset \mathbb{R}^r \), \( j = 1, \ldots, s \), are all basic semi-algebraic sets.

The reader will note that all constraints are linear constraints linking moments of the involved measures \( \phi_j \), \( j = 1, \ldots, s \) (whence the name of generalized moment problem). So the GMP is an infinite-dimensional LP on spaces of measures.

Of course GMP in (64) can be extended to more general functions and sets, but for a practical application of the Moment-SOS hierarchy, one needs algebraic data (polynomials and basic semi-algebraic sets). Notice also that formulation (4) of a polynomial optimization problem is the simplest instance of the GMP in which there is only one unknown measure \( \phi \) and only one (equality) moment-constraint \( \phi(S) = \int 1 d\phi = 1 \).

The dual GMP\(^*\) of (64) is also an infinite-dimensional LP, and when \( p := \#\Gamma < \infty \), it reads

\[
\text{GMP}^* : \sup_{\lambda \in \mathbb{R}^p} \left\{ \sum_{k=1}^p \lambda_k b_k : \right. \\
\text{s.t.} \quad f_j(x) - \sum_{k=1}^p \lambda_k h_{kj}(x) \geq 0, \quad \forall x \in S_j, \quad j = 1, \ldots, s \right. 
\]

Moment equality-constraints are also tolerated in (64) in which case the associated dual variable \( \lambda_k \) in (65) is not constraint to be nonnegative. As is the case in some important applications, the set \( \Gamma \) is also tolerated to be (countably) infinite. Finally, and not touched upon here, one may also tolerate as objective function of (64), a convex function of finitely many moments of measures \( \phi_j \) (e.g. \( -\log \det(M_n(\phi_j)) \)) of the moment matrix \( M_n(\phi_j) \).

As one next sees in two examples, in some applications the problem to solve is already under the format of an instance of a GMP (or GMP\(^*\)), whereas in other applications, some equivalent formulation the problem is an instance of the GMP. Strategy of the Moment-SOS hierarchy. Roughly speaking, to apply the Moment-SOS hierarchy to the GMP (64):

- One replaces the measures \((\phi_j)_{j=1,\ldots,s}\) by degree-2\(n\) truncated pseudomoment vectors \( \phi_j = (\phi_{j,\alpha}) \), \( \alpha \in \mathbb{N}^{2n}_r \), \( j = 1, \ldots, s \).
- One imposes semidefinite constraints on the moment and localizing matrices associated with each \( \phi_j \) and each set \( S_j \), which by Theorem 2.2(ii) are necessary conditions for \( \phi_j \) to be moments of a measure on \( S_j \).

Then as the moment constraints and the criterion are just linear on the pseudomoment vectors \( \phi_j \)'s, for each fixed \( n \) one ends up with a finite-dimensional semidefinite relaxation which provides a lower bound on the optimal value of the GMP. Similarly, to apply the Moment-SOS hierarchy to GMP\(^*\) in (65):

- For each \( j = 1, \ldots, s \), one replaces the positivity constraint

\[
f_j - \sum_{k=1}^p \lambda_k h_{kj} \geq 0 \quad \text{on } S_j,
\]
with a Putinar certificate of positivity of degree $2n$; see Theorem 2.2(i). For instance, if $S_j = [-1, 1]^d$ then the above positivity constraint reads:

$$f_j - \sum_{k=1}^p \lambda_k h_{kj} = \sum_{j=0}^d \sigma_j (1 - x_j^2); \quad \sigma_j \in \Sigma[x]_{n-d_j}, \ j = 0, \ldots, d.$$ 

Then as the criterion $\sum_k \lambda_k b_k$ is linear, one ends up with a finite-dimensional semidefinite program, which is the dual of the one on pseudo-moment vectors. In fact, a primal-dual semidefinite solver will solve both of them at the same time.

For sake of completeness, below are two illustrative applications of the above strategy. In the first example in computational geometry and probability, the problem itself is described as a GMP while in the second example in optimal control (OCP), an alternative and so-called “weak formulation” of the OCP is an instance of the GMP.

6.1. **Illustration in Probability and Computational Geometry.** Let $S \subset \mathbb{R}^d$ be compact set and suppose that $S \subset B := [-1, 1]^d$ (possibly after scaling). The goal is approximate the Lebesgue volume $\text{vol}(S)$ of $S$, as closely as desired. This is known to be a very hard problem. In fact even if $S$ is convex, approximating its volume is quite hard; see e.g. [24], the discussion in [39], and references therein.

Let $\lambda$ be the Lebesgue measure on $[-1, 1]^d$, so that its (infinite) vector of moments $\lambda = (\lambda_\alpha)_{\alpha \in \mathbb{N}^d}$ is available in closed form. Let $1 \in \mathbb{R}[x]$ be the constant polynomial (equal to 1 for all $x$) and for two measures $\mu, \nu$ on $\mathbb{R}^d$, the notation $\nu \leq \mu$ stands for $\nu(B) \leq \mu(B)$ for all $B \in B(\mathbb{R}^d)$.

**Proposition 6.1.** $\text{vol}(S) = \max_{\phi \in \mathcal{M}(S)_+, \nu \in \mathcal{M}_+(B)} \{ \phi(1) : \phi + \nu = \lambda \}$, and $\phi^* := 1_S \lambda$ is the unique optimal solution.

**Proof:** As $\phi + \nu = \lambda$, $\phi \leq \lambda$ and since supp$(\phi) \subseteq S$, $\phi(1) = \phi(S) \leq \lambda(S) = \text{vol}(S)$.

Next, with $\phi^* := 1_S \lambda \in \mathcal{M}(S)_+$, and $\nu^* := \mu - \phi^* \in \mathcal{M}_+(B)_+$, one obtains $\phi^*(1) = \lambda(S) = \text{vol}(S)$. \(\square\)

The above formulation of $\text{vol}(S)$ as an optimization problem is not yet in the format of an instance of the GMP (64). But notice that since $B$ is compact, $\phi + \nu = \lambda \iff \phi_\alpha + \nu_\alpha = \lambda_\alpha, \ \forall \alpha \in \mathbb{N}^d,$

and therefore

$$\text{vol}(S) = \max_{\phi \in \mathcal{M}(S)_+, \nu \in \mathcal{M}_+(B)_+} \{ \phi(1) : \phi_\alpha + \nu_\alpha = \lambda_\alpha, \ \forall \alpha \in \mathbb{N}^d \},$$

which is an instance of the GMP (64) with $\Gamma = \mathbb{N}^d$ (a countable set). We next see how to implement the moment-SOS hierarchy. Let $g_0 = 1$,

$$S = \{ x \in \mathbb{R}^d : g_j(x) \geq 0, \ j = 1, \ldots, m \},$$

and recall that $d_j = [\deg(g_j)/2]$ for all $j = 0, \ldots, m$. For each $n \in \mathbb{N}$, consider the optimization problem

$$\tau_n = \max_{\phi, \nu} \{ \phi_0 : \phi_\alpha + \nu_\alpha = \lambda_\alpha, \ \forall \alpha \in \mathbb{N}^d_{2n}; \ M_{n-d_j}(g_j \cdot \phi) \geq 0, \ j = 0, \ldots, m; \ M_n(\nu) \geq 0 \}. $$

For each fixed \( n \), (67) is a semidefinite program and an obvious relaxation of (66) so that \( \tau_n \geq \text{vol}(S) \) for all \( n \).

**Theorem 6.2** ([39]). The sequence of optimal values \( (\tau_n)_{n \in \mathbb{N}} \) is monotone non increasing, bounded below, and \( \lim_{n \to \infty} \tau_n = \text{vol}(S) \) as \( n \) grows.

So (67) indexed by \( n \in \mathbb{N} \), provides a hierarchy of semidefinite relaxations of (66) such that \( (\tau_n)_{n \in \mathbb{N}} \) converges (from above) to the desired value \( \text{vol}(S) \) as \( n \) increases. However in its basic form (67) its convergence is quite slow. To see why, consider the dual of (67), which is the semidefinite program

\[
\tau_n^* = \min_{p \in \mathbb{R}[x]_{2n}} \left\{ \int_B p \, d\lambda : p - 1 = \sum_{j=0}^m \sigma_j g_j \right\}
\]

It turns out that if \( S \) has nonempty interior then \( \tau_n = \tau_n^* \) for all \( n \). Next observe that

\[
p \in \Sigma[x]_n \text{ and } p - 1 = \sum_{j=0}^m \sigma_j g_j \Rightarrow p \geq 1_S, \quad \forall x \in B,
\]

and since \( \int p \, d\lambda \downarrow 1_S d\lambda \) as \( n \) grows, in the dual (68) one searches of a degree-\( 2n \) SOS polynomial \( p \) that tries to approximate from above, the indicator function of \( S \) for all \( x \in B \). As is well-known, for such polynomial approximations a typical Gibbs phenomenon (oscillations) occurs at points of discontinuities, which makes the convergence quite slow; see Figure 6.1.

**Figure 6.1.** \( S = [-0.5, 0.5] \subset [0, 1] \); polynomial approximation (in red) of \( 1_S \) on \( [0, 1] \) with Gibbs phenomenon

Fortunately one may significantly attenuate (or even remedy to) this problem. Indeed as one knows in advance the (unique) optimal solution \( \phi^* = 1_S \lambda \) of (66), every available additional information on \( \phi^* \) in terms of linear constraints on its moments can be added to (66) without changing its optimal value and solution. While such additional redundant constraints do not change (66), they have a dramatic impact on the relaxations (67) and yield a quite significant acceleration of their convergence. And it is indeed the case when one adds additional moment constraints (satisfied by \( \phi^* \)) coming from Stokes’ theorem.
Stokes constraints. Let us see how it works for the case where \( S = \{ x : g(x) \geq 0 \} \) for some polynomial \( g \in \mathbb{R}[x] \) with compact sublevel set \( S \). As \( g \) vanishes on \( \partial S \), by Stokes’s theorem,

\[
\int_S \text{Div}(x g(x) x^\alpha) \, dx = \int_{\partial S} \langle \vec{n}_x, x \rangle g(x) x^\alpha \, d\sigma(x) = 0, \quad \forall \alpha \in \mathbb{N}^d,
\]

where \( \vec{n}_x \) is the outward pointing normal at \( x \in \partial S \). Hence each \( \alpha \in \mathbb{N}^d \) provides us with the moment constraint

\[
\phi^*(s_\alpha) := \phi^*(\text{Div}(x g(x) x^\alpha)) = 0,
\]
on \( \phi^* \), because \( x \mapsto s_\alpha(x) := \text{Div}(x g(x) x^\alpha) \) is a polynomial (of degree \( \text{deg}(g) + |\alpha| + 1 \)). Hence for every \( n \in \mathbb{N} \), the additional moment constraints

\[
(69) \quad \phi(s_\alpha) = 0, \quad \forall \alpha : |\alpha| \leq 2n - 1 - \text{deg}(g),
\]
can be included in the semidefinite relaxation (67). The effect on the dual (68) is to change the initial constraint \( p - 1 = \sigma_0 + \sigma_1 \, g \), to now

\[
p + q - 1 = \sigma_0 + \sigma_1 \, g,
\]
where \( q := \sum_{|\alpha| \leq 2n - \text{deg}(g) - 1} \theta_\alpha \, s_\alpha \) for the dual variables \( (\theta_\alpha) \) associated with (69). Hence now \( p \) is not required anymore to approximate \( 1_S \) from above! For more details on volume computation via the moment-SOS hierarchy, the interested reader is referred to [39], [129], and [128]. In particular, this technique has also been implemented in [129] for approximating the volume of certain non-convex sets \( S \subset \mathbb{R}^{100} \) where the description of \( S \) exhibits some structured sparsity, as described in Section 3.8.

**Remark 6.3.** One can consider (66) with a measure \( \lambda \) different from Lebesgue measure on \( B \). For example with \( \lambda \) being the Gaussian measure \( \exp(-||x||^2)dx \) on \( \mathbb{R}^d \), or the exponential measure \( \exp(-\sum j \, x_j) dx \) on \( \mathbb{R}_+^d \), one may approximate the value \( \lambda(S) \) for non-compact semi-algebraic sets, as closely as desired; see e.g. [64].

Application in probability. Suppose that \( X \) is a \( \mathbb{R}^d \)-valued random vector whose distribution is only partially known through a few of its moments \( m = (m_\alpha)_{\alpha \in \Gamma} \), where \( \Gamma \subset \mathbb{N}^d \) is a finite set (typically the index set of moments up to order 3,4). Next, let \( S \subset \mathbb{R}^d \) be a given compact basic semi-algebraic set with nonempty interior. The goal is to provide the best upper bound on \( \text{Prob}(X \in S) \), under the partial knowledge of \( m = (m_\alpha)_{\alpha \in \Gamma} \), that is, compute:

\[
(70) \quad \rho = \max_{\mu \in \mathcal{M}(\mathbb{R}^d)_+} \{ \mu(S) : \int x^\alpha \, d\mu = m_\alpha, \, \forall \alpha \in \Gamma \}.
\]

Observe that (70) is an instance of the GMP (64) but with non-polynomial data because with \( \mu \in \mathcal{M}(\mathbb{R}^d)_+ \), \( \mu(S) = \mu(1_S) \) and \( 1_S \) is not a polynomial. We need consider that \( \mu = \phi + \nu \) with \( \phi \in \mathcal{M}(S)_+ \) (in which case \( \phi(S) = \phi(1) = \phi_0 \)), and so for every \( n \in \mathbb{N} \), consider the optimization problem,

\[
(71) \quad \tau_n = \max_{\phi, \nu} \{ \phi_0 : \phi_\alpha + \nu_\alpha = m_\alpha, \quad \forall \alpha \in \Gamma; \quad M_{n-d_j}(g_j \cdot \phi) \geq 0, \quad j = 0, \ldots, m; \quad M_n(\nu) \geq 0 \},
\]
which is a relaxation of (70) and a variant of (67) (in fact even easier because now \( \Gamma \) is a finite set instead of the countable set \( \mathbb{N}^d \)). For instance with \( \Gamma = \mathbb{N}_2^d \) for some fixed \( t \), the dual of (71) reads:

\[
\tau^*_n = \min_{p} \left\{ \sum_{a \in \Gamma} p_\alpha m_\alpha : p - 1 = \sum_{j=0}^{m} \sigma_j g_j \quad p \in \Sigma[\mathbf{x}]_I; \quad \sigma_j \in \Sigma[\mathbf{x}]_{n-d_j} : j = 0, \ldots, m \right\}.
\]

The difference with (68) is that now, even when \( n \) changes one still searches for a degree-2\( t \) polynomial \( p \geq 1_S \) (where the degree 2\( t \) is fixed by the number of moments in \( \Gamma \)). In this case we do not have a Gibbs phenomenon because the degree of \( p \) is fixed.

Next, let \( \Phi := \{ \mu \in \mathcal{M}(\mathbb{R}^d_+) : \int x^\alpha \, d\mu = m_\alpha, \quad \forall \alpha \in \Gamma \} \). If there is some \( \mu \in \Phi \) with a strictly positive density w.r.t. Lebesgue measure, and with all moments finite, then each relaxation (72) is solvable and there is no duality gap, i.e., \( \tau_n = \tau_n^* \) and there is an optimal solution \( p^* \in \mathbb{R}[\mathbf{x}]_I \) for all \( n \). Moreover \( \tau_n \downarrow \tau \geq \rho \) as \( n \to \infty \). Finally, the bound \( \tau \) may be sharp, i.e., \( \tau = \rho \) if at some step \( n \), the moment matrices of an optimal solution \((\phi, \nu)\) of (71) satisfy some “flatness” property; for more details see e.g. [56] and [14].

### 6.2. Illustration in optimal control of dynamical systems.

In this section one briefly describes how to apply the Moment-SOS hierarchy to help solve optimal control problems (OCP) with algebraic data, i.e., whose description is through polynomials and basic semi-algebraic sets. Consider the optimal control problem:

\[
\text{OCP : } J(x_0, 0) := \min_u \left\{ \int_0^1 h(x(t), u(t)) \, dt + H(x(1)) \right\},
\]

s.t. \( x(t) = f(x(t), u(t)), \quad \forall t \in (0, 1) \)
\( x(t) \in X, \ u(t) \in U, \quad \forall t \in (0, 1) \)
\( x(0) = x_0 \),

where \( h, H, f \) are polynomials and \( X \subset \mathbb{R}^d \) and \( U \subset \mathbb{R}^m \) are basic semi-algebraic set, and \( x_0 \in X \) is the initial condition.

Eq. (73) describes a dynamical system whose evolution in the time interval [0, 1] of its state \( x(t) \in \mathbb{R}^d, t \in [0, 1] \), is governed by a controlled ordinary differential equation (o.d.e.) with vector field \( f : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \), and control \( u(t) \in U \) for all \( t \in (0, 1) \). The goal is to approximate an optimal (or close to optimal) control trajectory \( t \mapsto u^*(t) \in \mathbb{R}^m, t \in [0, 1] \), which minimizes the functional \( \int_0^1 h(x(t), u(t)) \, dt + H(x(1)) \). We here do not discuss the appropriate function spaces in which one has to search the state and control trajectories \( x(t), u(t) \), but rather to show

- (i) how to model (73) as a particular instance of the GMP (64), and
- (ii) how to define an appropriate Moment-SOS hierarchy for solving (73).

It is important to emphasize that in contrast to POPs where one searches for a point \( x^* \in S \subset \mathbb{R}^d \), one now searches for maps \( (x^*, u^*) : [0, 1] \to \mathbb{R}^d \times \mathbb{R}^m \), a much more difficult problem which is already infinite-dimensional in its description.
Strategy. As for (static) optimization problems (1) where in the Moment-SOS hierarchy one searches for a probability measure (the Dirac measure \( \delta_{x^*} \) at a global minimizer \( x^* \in S \)), here one will also searches for a measure \( \mu \), now supported on an optimal state-control trajectory \( \{(x(t), u(t)) : t \in [0, 1]\} \) from time \( t = 0 \) up to time \( t = 1 \).

By integrating polynomial test functions along feasible trajectories, the ordinary differential equation that governs the dynamical system will provide linear constraints on moments of \( \mu \) and moments of a terminal measure \( \nu \) on \( X \) at time \( t = 1 \) (because the vector field \( f \) in (73) is a polynomial). The state and control constraints in (73) translate into support constraints on \( \mu \) and \( \nu \).

Modeling (73) as a GMP via occupation measures. The idea is to look at (73) via its impact on the evaluation of test functions all along feasible trajectories. Let \( \{(x(t), u(t)) : t \in [0, 1]\} \) be an admissible trajectory, and let \( (x, t) \mapsto w(x(t), t) \) be an arbitrary test function in \( \mathcal{C}^1(X \times [0, 1]) \): Then observe that

\[
(74) (x(1), 1) - w(x(0), 0) = \int_0^1 dw(x(t), t) = \int_0^1 \frac{\partial w(x(t), t)}{\partial t} + \langle \nabla_x w(x(t), t), f(x(t), u(t)) \rangle \, dt.
\]

Introduce the measures \( \mu \) on \( X \times U \times [0, 1] \), and \( \nu, \nu_0 \) on \( X \times [0, 1] \):

\[
(75) \mu(A \times B \times C) = \int_{[0, 1]}^1 1_{A \cap X}(x(t)) 1_{B \cap U}(u(t)) \, dt
\]

\[
(76) \nu(A \times C) = 1_{(A \cap X) \times \{0\}}(x, t)
\]

\[
(77) \nu_0(A \times C) = 1_{(A \cap X) \times \{1\}}(x, t),
\]

for all Borel sets \( A \in \mathcal{B}(X) \), \( B \in \mathcal{B}(U) \), and \( C \in \mathcal{B}([0, 1]) \). The measure \( \mu \) is called the occupation measure up to time 1 while \( \nu_0 \) (resp. \( \nu \)) is called the occupation measure at time \( t = 0 \) (resp. at time \( t = 1 \)), all associated with the trajectory \( \{(x(t), u(t)) : t \in [0, 1]\} \). Another equivalent characterization of \( \mu \) is via its disintegration

\[
(78) d\mu(x, u, t) = \delta_{\{(x(t), u(t))\}}(d(x, u)) 1_{[0, 1]}(t) \, dt,
\]

into:

- its marginal \( 1_{[0, 1]}(t) \) on \( [0, 1] \), and
- its conditional probability \( \delta_{\{(x(t), u(t))\}}(d(x, u)) \) on \( X \times U \), given \( t \in [0, 1] \) (which is the Dirac measure at the point \( (x(t), u(t)) \in X \times U \)).

Importantly, observe that the support of \( \mu \) is the graph \( \{(t, x(t), u(t)) : t \in [0, 1]\} \) of state-control trajectories \((x(t), u(t))\). Ideally one searches for the measure

\[
(79) d\mu^*(x, u, t) = \delta_{\{(x^*(t), u^*(t))\}}(d(x, u)) 1_{[0, 1]}(t) \, dt,
\]

whose support is precisely the graph of optimal state-control trajectories \((x^*(t), u^*(t))\), \( t \in [0, 1] \) (when the latter exist).
The moment-SOS hierarchy: Applications and related topics

One reason why one introduces occupation measures is that the time integral (74) reads as the spatial integral

$$\int w \, dv - \int w \, dv_0 = \int \frac{\partial w}{\partial t}(x, t) + (\nabla_x w(x, t), f(x, u)) \, d\mu(x, u, t),$$

where the variables $(x, u, t)$ are now treated as independent variables. The respective dependence of $(x - u - t)$ is implicit through the support of $\mu$.

Next, introduce the operator $L : \mathcal{C}^1(X \times [0, 1]) \to \mathcal{C}(X \times U \times [0, 1])$:

$$w \mapsto Lw := \frac{\partial w}{\partial t} + (\nabla_x w, f),$$

and its adjoint $L^* : \mathcal{C}(X \times U \times [0, 1]^* \to \mathcal{C}^1(X \times [0, 1])^*$ by:

$$\mu \mapsto L^* \mu := -\frac{\partial \mu}{\partial t} - \sum_{i=1}^d \frac{\partial(f_i \mu)}{\partial x_i} = -\frac{\partial \mu}{\partial t} - \text{div}(f \mu),$$

where derivatives of measures are understood in a weak sense via their actions on smooth test functions (and the change of signs comes from integration by parts).

Then (79) reads

$$\langle w, \nu \rangle - \langle w, v_0 \rangle = \langle Lw, \mu \rangle = \langle w, L^* \mu \rangle,$$

and as it must be valid for all test functions $w$ in a dense subset $D \subset \mathcal{C}^1(X \times [0, 1])$, one obtains the equation $L^* \mu = \nu - v_0$, i.e.,

$$\frac{\partial \mu}{\partial t} + \text{div}(f \mu) + \nu = v_0.$$

Eq (80) is a linear transport equation (transporting $v_0$ to $\nu$) which is classical in fluid mechanics, statistical physics and PDEs. It is known under several names, as equation of conservation of mass, advection equation or Liouville’s equation.

This observation yields to define the so-called measure-valued weak formulation of OCP:

$$\rho = \inf_{\mu \vdash \nu} \int h \, d\mu + \int H \, dv$$

$$\text{s.t. } \int \frac{\partial w}{\partial t} + (\nabla_x w, f) \, d\mu = \int w \, dv - \int w \, dv_0, \forall w \in D;$$

$$\mu \in \mathcal{M}(X \times U \times [0, 1]), \nu \in \mathcal{M}(X),$$

introduced by [134].

Observe that if $D$ is a countable set of polynomials then (81) is an instance of the GMP in (64) and of course a relaxation of (73) so that $\rho \leq J$. The dual of (81) reads

$$\rho^* = \sup_{w \in \mathcal{C}^1(X \times [0, 1])} \int w \, dv_0 (w(x_0, 0)) :$$

$$\text{s.t. } h + Lw \geq 0, \forall (x, u, t) \in X \times U \times [0, 1];$$

$$w(x, 1) \leq H(x), \forall x \in X.$$

It turns out that under some convexity assumptions, $\rho = J(x_0, 0)$, i.e., the measure-valued weak formulation (81) is equivalent to the strong formulation (73). In the dual (82) one approximates the optimal value function $J : X \times [0, 1] \to \mathbb{R}$ all
along an optimal trajectory \( \{(x^*(t), t) : t \in [0, 1]; x^*(0) = x_0 \} \) (but not for all \((x, t) \in X \times [0, 1]\)). For more details see e.g. [68], [47], and references therein.

Next, to implement the moment SOS hierarchy one first selects a countable set of test functions \( \mathcal{D} \), namely the set of monomials

\[
\mathcal{D} := \{ (x^\alpha u^\beta t^k) : \alpha \in \mathbb{N}^d, \beta \in \mathbb{N}^m, k \in \mathbb{N} \},
\]

which is dense in \( \mathcal{C}^1(X \times [0, 1]) \). Then for every \( n \in \mathbb{N} \), let \( \mathcal{D}_n := \{(x^\alpha u^\beta t^k) \in \mathcal{D} : |\alpha + \beta| + k \leq 2n \} \), and consider the optimization problem:

\[
\rho_n = \min_{\mu, \nu} \mu(h) + \nu(H)
\]

s.t.

\[
\mu \left( \frac{\partial h}{\partial t} + \langle \nabla_x w, f \rangle \right) = \nu(w) - v_0(w), \quad \forall w \in \mathcal{D}_n;
\]

\[
M_n(\mu) = M_n(\nu) \geq 0;
\]

\[
M_{n-d_g}(g \cdot \mu) = M_{n-d_g}(g \cdot \nu) \geq 0, \quad \forall g \in G;
\]

\[
M_{n-1}(t(1-t) \cdot \mu) = M_{n-1}(\theta \cdot \mu) \geq 0, \quad \forall \theta \in \Theta.
\]

(83)

where \( X = \{x : g(x) \geq 0, g \in G\} \), \( U = \{u : \theta(u) \geq 0, \theta \in \Theta\} \), \( d_g = \lfloor \deg(g)/2 \rfloor \), \( g \in G \), and \( d_\theta = \lfloor \deg(\theta)/2 \rfloor, \theta \in \Theta \).

So the sequence of optimal values \( (\rho_n)_{n \in \mathbb{N}} \) is monotone non-decreasing and under the convexity assumptions alluded to above, \( \rho_n \uparrow J(x_0, 0) \) as \( n \to \infty \).

Reconstruction of optimal trajectories from moments. So far, by solving the semi-definite relaxations (83) one obtains a sequence \( (\rho_n)_{n \in \mathbb{N}} \) of lower bounds on the optimal value \( J \) of the initial OCP (73). But from the vector of pseudo-moments \( (\mu^0, \nu^0) \) optimal solution of (83) for some degree \( n \), one can retrieve or approximate optimal trajectories \( (x^*(t), u^*(t)) \) when they exist, or provide \( \epsilon \)-suboptimal trajectories otherwise?

Again and ideally, when \( n \) is sufficiently large, one expects that \( (\mu^0, \nu^0) \) approximates quite well moments of the measures

\[
d\mu(x, u, t) = \delta_{\{x^*(t), u^*(t)\}}(d(x, u)) 1_{[0, 1]}(t) \, dt,
\]

and \( \nu \) supported respectively on the trajectories \( (x^*(t), u^*(t)) \) and on the point \((x^*(1), 1) \in X \times \{1\}\). In Section 7.3 one describes an efficient strategy via the Christoffel function, a tool from approximation theory and orthogonal polynomials, particularly well suited to identify the support of a measure from the sole knowledge of its moments.

6.3. Other applications. We here provide the reader with some references to other applications of the Moment-SOS hierarchy. The purpose of this list which is not exhaustive, is to convince the reader that indeed the Moment-SOS hierarchy is a versatile tool, widely applicable as soon as the problem data are algebraic, and provided that some sparsity and/or symmetries can be exploited when the problem size demands.

- In control and stochastic control: [110], [36], [106, 109, 4, 108], [46], [29], [33].
- For convex computation of region of attraction for dynamical systems, see e.g. [37, Chapter 10], and for analysis and control of some types on non-linear PDEs, see e.g. [87], [37, Chapter 11] and [47].
• In tensor computation: [98], [101], [27], [97].
• In algorithmic game theory: [127], [53], [100].
• In management of energy networks, and in particular the for solving the Optimal Power Flow Problem (OPF) problem for (large) electricity networks. The Moment-SOS hierarchy has been able to handle problems with thousands variables by exploiting some inherent sparsity, in the spirit of Section 3.8; see e.g. [89], [130], [88], [19], [35].
• In Computer Science, e.g., for coding, packing problems: [8], [7], [22], [51].
• In Computer Vision, Geometric perception and Pattern Recognition: [140], [143], [142], [112].
• In mathematical finance for portfolio optimization and option pricing see [72], [31]. When the evolution in time is modeled by Ito’s stochastic differential equations, a weak formulation of the problem via occupation measures, is almost identical to that of OCPs with the only difference that a second-order differential operator appears in the infinitesimal generator. It is also the case for computing exit-time distribution (of a given set) in stochastic models as described in e.g. [71].

6.4. Notes and Sources. Section 6.1 is based on [56] and [39] while Section 6.2 is based on [68]. Infinite-dimensional LP formulations of optimal control problems can be traced back to works of L.C. Young, A.F. Filippov R.V. Gamkrelidze, J. Warga; see [30] for a historical survey. The novelty is the observation that such problems (with algebraic data) can be approximated numerically by semidefinite relaxations. In particular it should be noted that while state-constraints \( x(t) \in X \) for all \( t \)“, are usually considered a source of additional difficulties for classical numerical methods, they pose no problem for the Moment-SOS hierarchy as they simply appear in the support of the occupation measure.
The Moment-SOS hierarchy approach to analysis and control of some Non-Linear PDEs in [47] follows same principles as for solving OCPs. Namely on considers a measure-valued weak formulation of the problem, similar as the one in (81) for OCP’s, using test functions and occupation measures. Appropriate conditions are required for the weak formulation to be equivalent to the initial (strong) formulation. For instance for the Burgers equation, additional entropy constraints (due to Kruzkhov) on the occupation measures are needed; see [87] and [37, Chapter 11].

The reconstruction technique of state and control trajectories based on the Christoffel function is detailed in [86]. In particular, this technique has been used with success in [87] to recover solutions to Burgers PDE from moments of the measure supported on their graph. A (remarkably accurate) approximation of such moments have been obtained by solving semidefinite relaxations of the Moment-SOS hierarchy applied to the weak measure-valued formulation of Burgers equation (and in spirit similar to (83) for optimal control problems). The role and remarkable properties of the Christoffel function to recover a function from the sole knowledge of moments of the (degenerate) measure supported on its graph, is also treated in more details in Section 7.

7. Positive polynomials and Christoffel function

In this section one introduces the Christoffel-Darboux (CD) kernel and the Christoffel function (CF) which are classical tools from the fields of orthogonal polynomials and approximation theory. In addition of being interesting in their own right,
- they prove to be useful to understand and interpret the Moment-SOS hierarchy of lower bounds,
- the CF also appears in a certain distinguished representation of polynomials that are positive on a semi-algebraic set $S \subseteq \mathbb{R}^d$ as in (13), extensively used in the Moment-SOS hierarchy. In particular, every SOS polynomial $p$ in the interior of the convex cone $\Sigma[x]_n$ of degree-$2n$ SOS polynomials, is the reciprocal of the CF of some linear functional $\phi$ in $\mathbb{R}[x]_{2n}$. If $n = 2$ then $\phi$ has a clear interpretation in terms of a Gaussian measure but in the general case, the link between $p$ and $\phi$ is only partially understood and remains to be interpreted.

7.1. Christoffel-Darboux kernel and Christoffel Function. The CF is usually defined for a measure $\mu$ with moments $\mu = (\mu_\alpha)_{\alpha \in \mathbb{N}^d}$ whose support $S \subseteq \mathbb{R}^d$ is compact and such that its moment matrix $M_n(\mu)$ (or equivalently, $M_n(\mu)$) is positive definite for every degree $n \in \mathbb{N}$. However it can be also defined for a Riesz linear functional $\phi \in \mathbb{R}[x]^*$ (with $\phi = (\phi_\alpha)_{\alpha \in \mathbb{N}^d}$) such that $M_n(\phi) > 0$ for every $n \in \mathbb{N}$, not necessarily coming from a measure $\mu$.

So after fixing some ordering of monomials in $\mathbb{N}^d$, and since $M_n(\phi) > 0$ for every $n$, let $(P_\alpha)_{\alpha \in \mathbb{N}^d}$ be a family of polynomials that are orthonormal w.r.t. $\phi$, that is, such that

\begin{equation}
\phi(P_\alpha P_\beta) = \delta_{\alpha=\beta}, \quad \forall \alpha, \beta \in \mathbb{N}^d,
\end{equation}
where $\delta_{\alpha\beta}$ is the usual Kronecker symbol (with value 1, if $\alpha = \beta$ and 0 otherwise).

For every $n \in \mathbb{N}$, the Christoffel-Darboux (CD) kernel $K_n^\phi : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$ is then defined by:

$$
(85) \quad (x, y) \mapsto K_n^\phi(x, y) := \sum_{\alpha \in \mathbb{N}_0^d} P_{\alpha} (x) P_{\alpha} (y), \quad \forall x, y \in \mathbb{R}^d, \quad n \in \mathbb{N},
$$

and the Christoffel function (CF) $\Lambda_n^\phi : \mathbb{R}^d \to \mathbb{R}_+$ is defined by

$$
(86) \quad x \mapsto \Lambda_n^\phi(x) := K_n^\phi(x, x)^{-1}, \quad \forall x \in \mathbb{R}^d, \quad n \in \mathbb{N},
$$

i.e., the CF is the reciprocal of the “diagonal” of the CD kernel. Hence by construction $1/\Lambda_n^\phi$ is an SOS polynomial of degree $2n$.

**A reproducing property.** Let $p \in \mathbb{R}[x]_n$ and as $(P_{\alpha})_{\alpha \in \mathbb{N}_0^d}$ form a basis of $\mathbb{R}[x]_n$, write

$$
(87) \quad x \mapsto p(x) = \sum_{\alpha \in \mathbb{N}_0^d} p_{\alpha} P_{\alpha}(x) \quad \forall x \in \mathbb{R}^d,
$$

for some vector of coefficients $p = (p_{\alpha})_{\alpha \in \mathbb{N}_0^d}$ in $\mathbb{R}^{s(n)}$ (with $s(n) = \binom{n+\dim}{\dim}$).

With $x \in \mathbb{R}^d$ fixed, $y \mapsto K_n^\phi(x, y) \in \mathbb{R}[y]_n$, and we have

$$
\phi(K_n^\phi(x, \cdot) p) = \phi \left( \sum_{\alpha \in \mathbb{N}_0^d} P_{\alpha}(x) P_{\alpha}(y) \cdot \sum_{\beta \in \mathbb{N}_0^d} p_{\beta} P_{\beta}(y) \right)
= \sum_{\alpha \in \mathbb{N}_0^d} p_{\alpha} P_{\alpha}(x) = p(x), \quad \forall p \in \mathbb{R}[x]_n,
$$

where we have used that

$$
\phi(p_{\beta} P_{\beta}(y) P_{\alpha}(x) P_{\alpha}(y)) = p_{\beta} P_{\alpha}(x) \phi(P_{\beta} P_{\alpha}) = p_{\beta} P_{\alpha}(x) \delta_{\beta=\alpha}.
$$

For this reason, if $\mu$ is a measure on $S \subset \mathbb{R}^d$, and $L^2(\mu)$ is the Hilbert space of square integrable functions w.r.t. $\mu$, with scalar product

$$
\langle f, g \rangle = \int_S f \, g \, d\mu, \quad \forall f, g \in L^2(\mu),
$$

then $(\mathbb{R}[x]_n, \langle \cdot, \cdot \rangle)$ is $L^2(\mu)$ is called a Reproducing Kernel Hilbert Space (RKHS) with kernel $K^\mu_n$, because

$$
\int_S K_n^\mu(x, y) \, p(y) \, d\mu(y) = p(x), \quad \forall p \in \mathbb{R}[x]_n.
$$

**Alternative formulations of the CF.** Alternatively, the CF can be also be defined by:

$$
(88) \quad \Lambda_n^\phi(\xi) = \nu_n(\xi)^T M_n(\phi)^{-1} \nu_n(\xi), \quad \forall \xi \in \mathbb{R}^d,
$$

(the ABC theorem in [124]) and it also has the variational formulation:

$$
(89) \quad \Lambda_n^\phi(\xi) = \min_{p \in \mathbb{R}[x]_n} \{ \phi(p^2) : p(\xi) = 1 \}, \quad \forall \xi \in \mathbb{R}^d.
$$
In particular, observe that (89) can be rewritten
\[
\Lambda_n^\phi(\xi) = \min_{p \in \mathbb{R}^d} \{ p^T M_n(\phi) p : \langle p, v_n(\xi) \rangle = 1 \}, \quad \forall \xi \in \mathbb{R}^d,
\]
which is a convex quadratic optimization problem which can be solved efficiently even for large dimension \(d\). After some algebra, the unique optimal solution \(p^* \in \mathbb{R}[x]_n\) of (89) reads
\[
 x \mapsto p^*(x) = \frac{K_n^\phi(\xi, x)}{K_n^\phi(\xi, \xi)}, \quad \forall x \in \mathbb{R}^d.
\]

7.2. Some useful properties of the CF. A crucial property of the CFs \((\Lambda_n^\mu)n \in \mathbb{N}\) associated with a measure \(\mu\) on a compact set \(S \subset \mathbb{R}^d\), is to identify the support of \(\mu\). Indeed its decay with the degree \(n\) exhibits the following interesting dichotomy:
- \(\forall \xi \in \text{supp}(\mu), \Lambda_n^\mu(\xi)^{-1}\) grows at most as a polynomial in \(n\).
- \(\forall \xi \notin \text{supp}(\mu), \Lambda_n^\mu(\xi)^{-1}\) grows at least as an exponential in \(n\).

This property has been exploited in data analysis to provide a simple and easy-to-use tool (with no tuning of parameters), e.g. to detect outliers, with similar (and sometimes better) performance as state-of-the-art techniques; see [70, 69].

Next let \(\mu\) have a density \(f\) w.r.t. Lebesgue measure on \(S\). Under some additional regularity properties of \(\mu\) and its support \(S\),
\[
\lim_{n \to \infty} s(n) \Lambda_n^\mu(\xi) = f(\xi) / \mu_E(\xi),
\]
uniformly on compact subsets of \(\text{int}(S)\), where \(\mu_E\) is the density of a so-called equilibrium measure of \(S\).

Equilibrium measure. A Borel measure \(\mu\) supported on a compact set \(S \subset \mathbb{R}^d\) satisfies the Bernstein-Markov property if there exists a sequence of positive numbers \((M_n)n \in \mathbb{N}\) such that for all \(n\) and \(p \in \mathbb{R}[x]_n\),
\[
\sup_{x \in S} \|p(x)\| \leq M_n \cdot \left( \int_S p^2 d\mu \right)^{1/2}, \quad \text{and} \quad \lim_{n \to \infty} \log(M_n)/n = 0
\]
(see e.g. [70, Section 4.3.3]). The Bernstein-Markov property allows qualitative description for asymptotics of the Christoffel function as \(n\) grows.

The notion of equilibrium measure associated to a given set, originates from logarithmic potential theory (working in \(\mathbb{C}\) in the univariate case) to minimize some energy functional. For instance, the (Chebyshev) measure \(d\mu := dx / \pi \sqrt{1 - x^2}\) is the equilibrium measure of the interval \([-1, 1]\). Some generalizations have been obtained in the multivariate case via pluripotential theory in \(\mathbb{C}^d\). In particular if \(S \subset \mathbb{R}^d \subset \mathbb{C}^d\) is compact then its equilibrium measure (let us denote it by \(\lambda_S\)) is equivalent to Lebesgue measure on compact subsets of \(\text{int}(S)\). It has an even explicit expression if \(S\) is convex and symmetric about the origin; see e.g. [12] [13, Theorem 1.1 and Theorem 1.2]. Moreover if \(\mu\) is a Borel measure on \(S\) and \((S, \mu)\) has the Bernstein-Markov property (91) then the sequence of measures \(v_n = \frac{\mu}{s(n)\Lambda_n^\mu(x)}\),
\( n \in \mathbb{N}, \) converges to \( \Lambda_S \) for the weak-\( * \) topology and therefore in particular:

\[
\lim_{n \to \infty} \int_S x^\alpha \, dv_n = \lim_{n \to \infty} \int_S x^\alpha \, d\mu(x) - \int_S x^\alpha \, d\lambda_S, \quad \forall \alpha \in \mathbb{N}^d.
\]

(See e.g. [70, Theorem 4.4.4].) In addition, if the compact \( S \subset \mathbb{R}^d \) is regular then \( (S, \Lambda_S) \) has the Bernstein-Markov property. For a brief account on equilibrium mesures see [12, 13], the discussion in [70, Section 4.5, pp. 56–60] while for more detailed expositions see some of the references therein.

### 7.3. The CF for interpolation and approximation

In this section one briefly addresses the following issue which is interesting in its own right and is also central in the recovery of an optimal (or \( \varepsilon \)-optimal) trajectory \( \{x(t) : t \in [0, 1]\} \) in optimal control problems, from the sole knowledge of moments of the occupation measure supported on the graph \( \{(t, x(t)) : t \in [0, 1]\} \); see Section 6.2.

So with \( X \subset \mathbb{R}, \) let \( \mu \) be a measure on \([0, 1] \times X\), defined by

\[
d\mu(t, x) = \delta_{(f(t))}(dx) 1_{[0,1]}(t) \, dt,
\]

for some unknown measurable function \( f : [0, 1] \to X, \) i.e., \( \mu \) is supported on the graph \( \{(t, f(t)) : t \in [0, 1]\} \) of \( f \). The goal is to recover \( f \) from the sole knowledge of moments \( \mu = (\mu_{ij})_{(i,j) \in \mathbb{N}^2} \) where:

\[
\mu_{ij} = \int t^i x^j \, d\mu(t, x) = \int_0^1 t^i f(t)^j \, dt, \quad (i,j) \in \mathbb{N}^2.
\]

We propose to use the Christoffel function \( \Lambda_n^\mu \) to recover \( f \) from \( \mu \) because as seen before, \( \Lambda_n^\mu \) is a good tool to identify the support of \( \mu \), and in this case the support is precisely the graph of the unknown function \( f \) to recover. Here observe that \( \mu \) is a degenerate measure on \([0, 1] \times X\), i.e., its support has Lebesgue measure zero on \([0, 1] \times X\). Therefore its moment matrix \( M_n(\mu) \) can be ill-conditioned and even singular if \( f \) is a polynomial (because then the vector of coefficients of \( f \in \mathbb{R}[t] \) is in the kernel of \( M_n(\mu) \) when \( n \) is sufficiently large). So one first “perturbates” (or regularizes) \( M_n(\mu) \) to \( M_n(\mu) + \varepsilon \mathbf{I} \) with \( \mathbf{I} \) the identity matrix and some small regularization parameter \( \varepsilon > 0 \), and one defines a new perturbed Christoffel function \( \hat{\Lambda}_n^\mu \) by:

\[
(t, x) \mapsto \hat{\Lambda}_n^\mu(t, x)^{-1} := v_n(t, x)^T (M_n(\mu) + \varepsilon I)^{-1} v_n(t, x), \quad \forall (t, x) \in \mathbb{R}^2.
\]

Then define the following \( n \)-approximant \( f_n : [0, 1] \to X \) of \( f \) by:

\[
t \mapsto f_n(t) := \arg \min_{x \in X} \hat{\Lambda}_n^\mu(t, x)^{-1}, \quad t \in [0, 1].
\]

(In case of several minimizers in (94) then as a tie-breaker rule just take the smallest one.) For every fixed \( t \in [0, 1], \) computing \( f_n(t) \) can be done efficiently as \( x \mapsto \hat{\Lambda}_n^\mu(t, x)^{-1} \) is a univariate SOS polynomial in \( x \).

Next, as \( n \) increases, pointwise convergence (except at points of discontinuity) and \( L^1 \)-norm convergence to \( f \) are proved in [86]. Observe that the \( f_n \) approximant (94) is not a polynomial and being semi-algebraic, it is able approximate quite well some discontinuous functions with no Gibbs phenomenon.
For instance in Figure 7.3 (left) one may observe a typical Gibbs phenomenon (oscillations) when approximating the (discontinuous) step function \( t \mapsto f(t) = 0 \) if \( t \in [0, 1/2] \) and \( f(t) = 1 \) if \( t \in (1/2, 1] \) (in red) by a polynomial \( p^* \in \mathbb{R}[t]_n \) (in black) that minimizes the integral of the mean squared error, i.e.,

\[
p^* = \arg \min_{p \in \mathbb{R}[t]_n} \int_0^1 (p - f)^2 \, dt
\]

(even with degree \( n = 12 \)). This \( L^2 \)-norm approximation of \( f \) is a standard application of the CD-kernel \( K_\nu \) associated with the univariate measure \( \nu = f(t) \, dt \) on \([0, 1]\). On the other hand, with \( \varepsilon > 0 \) very small and \( f_\varepsilon \) as in (94), the step function is recovered almost exactly (in black) with no Gibbs phenomenon and with small degree \( n = 4 \). This is what one may call a non-standard application of the CD kernel as one considers the degenerate bivariate measure \( \mu \) on \( X \times [0, 1] \) instead of the univariate measure \( \nu = f(t) \, dt \) on \([0, 1]\).

Similarly in Figure 7.3, two discontinuous Eckhoff functions from [25] in red are also recovered (in black) with very good precision via \( f_\varepsilon \) in (94) with \( n = 10 \), and again with no Gibbs phenomenon; for more details the reader is referred to [86].

**Figure 7.1.** Left: Degree-12 polynomial approximation of step function with Gibbs phenomenon and right: step function approximated by \( f_4 \) in (94). © Reprinted from [86]

**Figure 7.2.** Two Eckhoff functions [25] approximated by \( f_{10} \) in (94). © Reprinted from [70]

Application to optimal control. As was already mentioned in Section 6.2, such a technique of approximation can be used to recover the graph of functions supported on trajectories \( \{(x^*(t), u^*(t)) : t \in [0, 1]\} \), optimal solutions of optimal control problems (73) described in Section 6.2. Indeed when applying the Moment-SOS
hierarchy to solve (73), at an optimal solution of (83) one obtains approximate moments up to degree $2n$, of the measure

$$ d\mu^*(x, u, t) = \delta_{\{x^*(t), u^*(t)\}} 1_{[0,1]}(t) \, dt, $$

supported on the graph of the map $(x^*, u^*) : [0, 1] \to \mathbb{R}^d \times \mathbb{R}^m$.

For instance, to recover the particular trajectory $\{x_i^*(t) : t \in [0, 1]\}$ for some coordinate $i \in \{1, \ldots, d\}$:

- Extract the sub-matrix $M_n^{(x_i, t)}$ of $M_n(\mu)$ obtained by restricting to rows and columns indexed by monomials $(x_i^0 t^j)$, $(k, j) \in \mathbb{N}_n^2$ (i.e., $M_n^{(x_i, t)}$ is the degree-$n$ moment matrix of the marginal $\mu_i$ of $\mu$ on $(x_i, t)$), and
- compute the perturbed Christoffel function in (93) associated with $\mu_i$, i.e.,

$$ \hat{\Lambda}^\mu_i(x_i, t)^{-1} = v_n(x_i, t)^T (M_n^{(x_i, t)} + \epsilon I)^{-1} v_n(x_i, t), $$

and then the $f_n$ approximant of the function $x_i(t)$ is obtained via (94).

The same procedure is repeated for all coordinates $x_i^*(t), i \in \{1, \ldots, d\}$, of $x^*(t)$, and all coordinates $u_j^*(t), j \in \{1, \ldots, m\}$, of $u^*(t)$, independently.

### 7.4. Christoffel function and positive polynomials.

One has first noticed that by construction, the reciprocal of a Christoffel function is an SOS polynomial. Next, with $S \subset \mathbb{R}^d$ as in (13), recall the convex cone

$$ Q_n(g) := \left\{ \sum_{j=0}^{\deg(g)/2} \sigma_j g_j : \sigma_j \in \Sigma[x]_{n-d_j}, j = 0, \ldots, m \right\}, $$

which is degree-$2n$ truncated version of the quadratic module $Q(g)$ (with $d_j = \lceil \deg(g_j)/2 \rceil$ and $g_0 = 1$). For every polynomial $p = \sum_j \sigma_j g_j \in Q_n(g)$, the SOS weights $\sigma_j$ provide $p$ with an algebraic certificate of its positivity on $S$.

Recall that the dual of $Q_n(g)$ is the convex cone

$$ Q^*_n(g) = \{ \phi \in \mathbb{R}^{\Sigma(2n)} : M_{n-d_j} (g_j \cdot \phi) \succeq 0, j = 0, \ldots, m \}, $$

where $M_n(g_j \cdot \phi)$ is the localizing matrix associated with the polynomial $g_j$ and the sequence $\phi$ (or equivalently the moment matrix associated with the sequence $g_j \cdot \phi$), defined in Section 2.1. One has seen that $Q_n(d)$ and its dual $Q^*_n(g)$ are crucial in the construction of the Moment-SOS hierarchy of lower bounds in Section 3. It turns out that there is a nice one-to-one correspondence between the respective interiors of $Q_n(g)$ and $Q^*_n(g)$, stated in terms of Christoffel functions.

**Theorem 7.1.** If $p \in \text{int}(Q_n(g))$ then there exists $\phi \in \text{int}(Q^*_n(g))$ such that

$$ p(x) = \sum_{j=0}^m \Lambda_{n-d_j}^{g_j \cdot \phi} (x)^{-1} g_j(x), \quad \forall x \in \mathbb{R}^d, $$

or, equivalently:

$$ \text{int}(Q_n(g)) = \left\{ \sum_{j=0}^m (\Lambda_{n-d_j}^{g_j \cdot \phi})^{-1} g_j : \phi \in \text{int}(Q^*_n(g)) \right\}. $$
Theorem 7.1 is an interpretation in [66] of a duality result of [92]. Remarkably, it states that every \( p \) in the interior of \( Q_n(g) \) has a distinguished certificate of its positivity on \( S \), with very specific SOS weights \( \sigma_j = (A^*_n\gamma_j)^{-1} \) in its Putinar’s representation (15). Indeed those weights are all coming from a unique element \( \phi \in \text{int}(Q^*_n(g)) \) and its Christoffel functions associated with the Riesz linear functionals \( g_j \cdot \phi, j = 0, \ldots, m \). It also turns out that those weights have an extremal property: Consider the optimization problem:

\[
\rho_n = \inf_{\phi \in \mathbb{R}^{(2n)}} \left\{ -\sum_{j=0}^m \log \det(M_{n-d_j}(g_j \cdot \phi)) : \phi(p) = 1, M_{n-d_j}(g_j \cdot \phi) \succeq 0, \forall j = 0, \ldots, m \right\},
\]

It is a convex optimization problem which has an explicit dual, namely

\[
\rho^*_n = \sup_{Q_j} \left\{ \sum_{j=0}^m \log \det(Q_j) : Q_j \succeq 0, \forall j = 0, \ldots, m \right\},
\]

where the supremum is taken over real symmetric matrices \( Q_j \) of respective size \( s(n-d_j), j = 0, \ldots, m \). The criterion to maximize in (100) is minus the log-barrier of the convex cone \( Q_n(g) \).

**Theorem 7.2.** With \( n \in \mathbb{N} \) fixed, Problems (99) and (100) have the same finite optimal value \( \rho_n = \rho^*_n \) if and only if \( p \in \text{int}(Q_n(g)) \). Moreover, both have a unique optimal solution \( \phi^*_n \in \mathbb{R}^{(2n)} \) and \( (Q_j^*)_{j=0}^m \) respectively, which satisfy \( Q^*_j = M_{n-d_j}(g_j \cdot \phi^*_n)^{-1} \) for all \( j = 0, \ldots, m \). And, as a consequence,

\[
p(x) = \frac{1}{\sum_{j=0}^m s(n-d_j)} \sum_{j=0}^m g_j(x) v_{n-d_j}(x)^T M_{n-d_j}(g_j \cdot \phi^*_n)^{-1} v_{n-d_j}(x)
\]

\[
(101) = \frac{1}{\sum_{j=0}^m s(n-d_j)} \sum_{j=0}^m g_j(x) A^*_n(\gamma_j)^{-1}, \forall x \in \mathbb{R}^d.
\]

Notice that \( \phi \) in (97) is just \( (\sum_{j=0}^m s(n-d_j)) \phi^*_n \) with \( \phi^*_n \) as in (101).

Of course, Theorem 7.1 immediately raises the following question: *given \( p \in \text{int}(Q_n(g)) \) what is this linear functional \( \phi \in \mathbb{R}[x]_{2n}^* \) with associated moment sequence \( \phi \in \mathbb{R}^{s(2n)} \) in Theorem 7.1?* It turns out that there is a simple and remarkable answer for special sets \( S \) and the constant polynomial \( p = 1 \).
Relating the constant polynomial and the equilibrium measure. Let $S \subset \mathbb{R}^d$ in (13) be a compact set with nonempty interior, generated by a finite set $	ilde{G} = \{g_1, \ldots, g_m\} \subset \mathbb{R}[x]$ of polynomials. Let $G \subset \mathbb{R}[x]$ be a certain finite set of polynomials formed with some products of polynomials in $	ilde{G}$. For instance

- If $S \subset \mathbb{R}^d$ is the Euclidean unit ball then $\tilde{G} = \{g\}$, $G = \{1, g\}$, with $x \mapsto g(x) = 1 - \|x\|^2$. Then the equilibrium measure $\mu$ is proportional to $\mathrm{d}x/\sqrt{1 - \|x\|^2}$.
- If $S$ is the unit box $[-1, 1]^d$ then $\tilde{G} = \{g_1, \ldots, g_d\}$ with $g_j(x) = 1 - x_j^2$, $j = 1, \ldots, d$, and $G = \{g_\varepsilon : \varepsilon \in \{0, 1\}^d\}$, where
  \[
  x \mapsto g_\varepsilon(x) := \prod_{j=1}^d g_j(x)^{\varepsilon_j}, \quad \forall x \in \mathbb{R}^d.
  \]

The equilibrium measure $\mu$ of $S$ is proportional to $\mathrm{d}x/\prod_{j=1}^d \sqrt{1 - x_j^2}$.

- If $S \subset \mathbb{R}^d$ is the canonical simplex then $\tilde{G} = \{g_1, \ldots, g_{d+1}\}$ with $g_j(x) = x_j$, $j = 1, \ldots, d$, $g_{d+1}(x) = 1 - \sum_j x_j$, and $G = \{g_\varepsilon : \varepsilon \in \{0, 1\}^{d+1}; |\varepsilon| \in 2\mathbb{N}\}$, where
  \[
  x \mapsto g_\varepsilon(x) := \prod_{j=1}^{d+1} g_j(x)^{\varepsilon_j}, \quad \forall x \in \mathbb{R}^d.
  \]

The equilibrium measure $\mu$ of $S$ is proportional to $\mathrm{d}x/\sqrt{(1 - \sum_j x_j) \prod_{j=1}^d x_j}$.

For every $g \in G$ let $t_g := \lfloor \deg(g)/2 \rfloor$. In addition, given $n \in \mathbb{N}$, let $G_n := \{g \in G : \deg(g) \leq 2n\}$ so that $G_n = G$ as soon as $n \geq \lceil d/2 \rceil$.

**Theorem 7.3** (67, 73). Let $S \subset \mathbb{R}^d$ be the Euclidean unit ball, the unit box, or the simplex, and let $\mu$ be its equilibrium measure. Then for all integer $n$:

\[
1 = \frac{1}{\sum_{g \in G_n} s(t - t_g)} \sum_{g \in G_n} g(x) \Lambda_{n-t_g}^\mu(x)^{-1}, \quad \forall x \in \mathbb{R}^d.
\]

So, remarkably, the constant polynomial $p = 1 \in \text{int}(Q_n(g))$ for all $n$, is strongly related to the equilibrium measure $\mu$ of $S$. Its corresponding element $\phi \in \text{int}(Q_n^*(g))$ in Theorem 7.1, is the moment vector $\mu \in \mathbb{R}^{s(2n)}$ of $\mu$.

In addition, for every $n$, the polynomials $(g/\Lambda_{n-t_g}^\mu)_{g \in G_n}$ (all nonnegative on $S$) provide $S$ with a polynomial partition of unity. We have called (102) a generalized polynomial Pell’s equation solved by the Christoffel functions $(\Lambda_{n-t_g}^\mu)_{g \in G_n}$ (and the polynomials $g \in G_n$) because (102) is an exact multivariate generalization of the polynomial Pell’s equation

\[
1 = T_n(x)^2 + (1 - x^2) U_{n-1}(x)^2, \quad \forall x \in \mathbb{R},
\]

\[\text{A triple } (F, g, H) \text{ of polynomials in } \mathbb{Z}[x] \text{ satisfy (polynomial) Pell’s equation if } F^2 + g H^2 = 1.\]
satisfied by the univariate Chebyshev polynomials of first kind \((T_n)_{n \in \mathbb{N}}\) and Chebyshev polynomials of second kind \((U_n)_{n \in \mathbb{N}}\). Indeed after normalization to orthonormal polynomials, and summing up (103) over \(n\), one obtains

\[
1 = \frac{1}{s(n) + s(n - 1)} \left( \Lambda^\mu_n(x)^{-1} + g(x) \Lambda^\mu_{n-1}(x)^{-1} \right), \quad \forall x \in \mathbb{R}, \ n \in \mathbb{N},
\]

where \(g(x) = 1 - x^2\), and \(d\mu(x) = dx/\pi \sqrt{1 - x^2}\) is the equilibrium measure of the interval \(S = [-1, 1]\). The term “generalized” is justified because in (102) one has sum-of-squares in \(\mathbb{R}^d\) and several generators \(g_2 G_n\), instead of two single squares in \(\mathbb{Z}[x]\) and a single generator \(g\) in (103). But formally, (102) is exactly of the same flavor as (104).

**Remark 7.4.** When \(S = \mathbb{R}^d\) there is still a nice well-known and somehow related fact. Let \(p \in \mathbb{R}[x]_2\) be a quadratic polynomial which is strictly positive on \(\mathbb{R}^d\). With \(v_1(x) = (1, x_1, \ldots, x_d)\), \(p\) is written as

\[
\mathbf{x} \mapsto p(\mathbf{x}) := v_1(\mathbf{x})^T Q v_1(\mathbf{x}), \quad \forall \mathbf{x} \in \mathbb{R}^d,
\]

for some (unique) Gram matrix \(Q > 0\). It is well-known that \(Q^{-1}\) is the moment matrix \(M_1(\mu)\) of a Gaussian measure \(\mu\) on \(\mathbb{R}^d\), and therefore

\[
p(\mathbf{x}) = \Lambda^\mu_1(\mathbf{x})^{-1}, \quad \forall \mathbf{x} \in \mathbb{R}^d.
\]

This is another particular case (but in a non-compact setting) where one is able to identify the linear functional \(\varphi\) in Theorem 7.1 (with now \(Q_1(g) = \Sigma[\mathbf{x}]_1^\mu = \{ \phi \in \mathbb{R}^{d+1} : M_1(\phi) \geq 0 \}\). For instance, the scaled Hermite polynomials of degree at most 1,

\[
\hat{H}_0(\mathbf{x}) = (2\pi)^{-d/4}, \quad \hat{H}_j(\mathbf{x}) = (2\pi)^{-d/4} x_j, \quad j = 1, \ldots, d,
\]

are orthonormal w.r.t. the Gaussian (product measure) \(d\mu(x) = \exp(-\sum_j x_j^2/2)\, dx\), and

\[
\Lambda^\mu_1(\mathbf{x})^{-1} = \sum_{j=0}^d \hat{H}_j(\mathbf{x})^2 = (2\pi)^{-d/2}(1 + \|\mathbf{x}\|^2).
\]

**7.5. Comparing Moment-SOS hierarchies of upper and lower bounds.** To compare the two Moment-SOS hierarchies of upper and lower bounds for solving the POP

\[
P: \quad f^* = \min \{ f(\mathbf{x}) : \mathbf{x} \in S \},
\]

one expresses them in the same language of polynomial densities w.r.t. a reference finite Borel probability measure \(\mu\) whose support is exactly the set \(S \subset \mathbb{R}^d\) (assumed to be compact with nonempty interior). Let \(\mathcal{P}(S)\) be the space of probability measures on \(S\), and let \((P_\alpha)_{\alpha \in \mathbb{N}^d}\) be a family of polynomials that are orthonormal w.r.t. \(\mu\).
Moment-SOS hierarchy of Lower bounds. With $\phi \in \mathbb{R}[y]_{2n}$ arbitrary, and from the reproducing property (87) of $K^\mu_{2n}$, observe that

$$
\phi(f) = \phi \left( \int_S \sum_{\alpha \in \mathbb{N}_{2n}^d} P_\alpha(y) P_\alpha(x) f(x) \, d\mu(x) \right)
$$

$$
= \sum_{\alpha \in \mathbb{N}_{2n}^d} \phi(P_\alpha) \int_S P_\alpha(x) f(x) \, d\mu(x)
$$

$$
= \int_S f(x) \left( \sum_{\alpha \in \mathbb{N}_{2n}^d} \phi(P_\alpha) P_\alpha(x) \right) \, d\mu(x) = \int_S f(x) \sigma_\phi(x) \, d\mu(x)
$$

where the degree-$2n$ polynomial

$$
(105) \quad x \mapsto \sigma_\phi(x) := \sum_{\alpha \in \mathbb{N}_{2n}^d} \phi(P_\alpha) P_\alpha(x),
$$

is a signed density w.r.t. $\mu$.

Next, recall that in the semidefinite relaxation (26) of the Moment-SOS hierarchy of lower bounds on $f^*$, one searches for a linear functional $\phi \in \mathbb{R}[x]_{2n}$ which satisfies

$$
\phi(1) = 1; \quad M_{n-d_j} (g_j \cdot \phi) \succeq 0, \quad \forall j = 0, \ldots, m,
$$

and which minimizes $\langle f, \phi \rangle = \phi(f) = \int_S f \sigma_\phi \, d\mu$. Moreover, observe that

$$
1 = \phi(1) = \int_S \sigma_\phi \, d\mu,
$$

which means that $\sigma_\phi$ is a signed probability density. Therefore one has proved:

**Theorem 7.5.** Let $\mu$ be a finite Borel measure whose support is $S$ in (13) and consider the Moment-SOS hierarchy of semidefinite relaxations (26) for solving $P$. Then with $n$ fixed, (26) reads

$$
(106) \quad \min_{\phi \in \mathbb{R}[x]_{2n}} \{ \int_S f \sigma_\phi \, d\mu : \phi(1) = 1; \quad M_{n-d_j} (g_j \cdot \phi) \succeq 0, \quad j = 0, \ldots, m \},
$$

where $\sigma_\phi$ is the signed probability density w.r.t. $\mu$ in (105).

So, again, solving the semidefinite relaxation (26) in the Moment-SOS hierarchy is searching for a polynomial signed probability density $\sigma_\phi \in \mathbb{R}[x]_{2n}$ of the form (105), and as already mentioned, when the relaxation (26) is exact, $\phi^* = \delta_{\{y\}}$, where $y \in S$ is a global minimizer of $f$. Then the associated polynomial signed probability density $\sigma_{\phi^*} \in \mathbb{R}[x]_{2n}$ reads

$$
\sigma_{\phi^*}(x) = \sum_{\alpha \in \mathbb{N}_{2n}^d} P_\alpha(y) P_\alpha(x) = K^\mu_{2n}(y, x).
$$

It is interesting to visualize in Figure 7.5 how $\sigma_{\phi^*}$ looks like in the toy example where $S = [-1, 1]$ and $\mu = dx/2$. Indeed $\sigma_{\phi^*}$ has a peak at $x = y$, and so mimics the Dirac measure at $y$ (as long as moments up to degree $2n$ are concerned).
Comparing with the Moment-SOS hierarchy of upper bounds. Let $\mu$ be the same (reference) measure on $S$, as in Theorem 7.5. By construction, the (refined) hierarchy of upper bounds $(\hat{v}_n)_{n \in \mathbb{N}}$ in (58) is searching for a positive probability density $\sigma \in Q_n(g)$. Hence $x \mapsto \sigma(x) = \sum_{\alpha} \sigma_\alpha P_\alpha(x)$, with

$$1 = \int_S \sigma \, d\mu = \sum_{\alpha} \sigma_\alpha \int_S P_\alpha \, d\mu = \sigma_0,$$

as $P_0 = 1$ (because $\mu$ is a probability measure), and

$$\sigma \in Q_n(g) \Rightarrow \sum_{\alpha \in \mathbb{N}_n^d} \sigma_\alpha P_\alpha = \sum_{j=0}^m \psi_j g_j; \quad \psi_j \in \Sigma[x]_{n-d_j}, \ j = 0, \ldots, m.$$

As one may see, Table 7.5 exhibits a complete symmetry between the primal and dual formulations of the respective Moment-SOS hierarchies of lower bounds and upper bounds, when the involved polynomials are expressed in the orthonormal basis $(P_\alpha)_{\alpha \in \mathbb{N}^d}$. 

Figure 7.3. $S = [-1, 1]$, $\mu = dx/2$; the signed density $x \mapsto \sigma_\phi(x) = K^N_{2n}(x, y)$ with $y = 0$ (left), $y = 0.5$ (middle) and $y = 1$ (right). © Reprinted from [70]

### 7.6 Notes and sources.
Sections 7.1-7.2: For more details and historical background on the CD kernel and the Christoffel function, the interested reader is referred to [124, 93, 70] and references therein. Section 7.3 is based on [86] and [38]. Section 7.4 is essentially from [66, 67] and [73]. Remarkably, the generalized Pell’s equation establishes links between seemingly unrelated fields like optimization, positivity certificates, conic duality on one side, and orthogonal polynomials and equilibrium measures on the other side. It is likely that the generalized Pell’s equation is valid only for sets with specific geometries and with an appropriate set of generators. Indeed from the proof in [73], crucial is a property of Gegenbauer polynomials (in particular a summation property). However for more general basic
semi-algebraic sets $S$, there is still a weaker result that links the constant polynomial $1 \in Q_n(g)$ and moments $\phi \in Q^*_n(g)$ of the equilibrium measure $\mu$ of $S$; see [73].

In Section 7.5 one interprets both Moment-SOS hierarchies of upper and lower bounds in the common language of densities w.r.t. a reference measure $\mu$ whose support is $S$. In contrast to the hierarchy of upper bounds, finite convergence for the hierarchy of lower bounds is possible (and in fact takes place generically) because a signed density w.r.t. $\mu$ may have all its moments up to order $2n$ equal to those of the Dirac measure at a global minimizer, which is not possible for a positive density w.r.t. $\mu$ on $S$ (with nonempty interior) as in the hierarchy of upper bounds.

8. Conclusion

One has described the Moment-SOS hierarchy methodology for polynomial optimization (hierarchies of lower and upper bounds). It also applies solve the generalized Moment Problem (GMP) with algebraic data, whose list of applications in many area of Science and Engineering is almost endless. The basic principle behind the Moment-SOS hierarchy is quite simple and for illustration purpose we have described its application on two problems (viewed as instances of the GMP) in computational geometry and optimal control.

It is a powerful methodology but the computational cost of its basic formulation can be quite heavy even for problems of modest dimension. Fortunately, as large scale problems often exhibit sparsity and/or symmetries in their formulation, one has also described how such properties can be exploited to define a sparsity-adapted Moment-SOS hierarchy whose associated computational burden can be drastically reduced.

Much remains to be done in several research directions (some have been briefly mentioned). As it is at the crossroad of several disciplines, it is very likely that we should see more and more contributions in the coming years.
